The 14th annual international symposium Frontiers of Fundamental Physics is organized by the Labex OCEVU. It is held in Marseille, at the Faculty of Sciences of Aix-Marseille University (AMU).

FFP Symposium began in India in 1997 and it became itinerant in 2004, through Europe, Canada and Australia. It covers topics in fundamental physics with the objective to enable scholars working in related areas to meet on a single platform and exchange ideas. In addition to highlighting the progress in these areas, the symposium invites the top researchers to reflect on the educational aspects of our discipline. Moreover, the scientific concepts are also discussed through philosophical and epistemological viewpoints. Several eminent scientists, such as the laureates of prestigious awards (Nobel, Fields Medal,...), have already participated in these meetings.

FFP14 develops around seven main themes, which are

- Astroparticle Physics
- Cosmology
- High Energy Physics
- Quantum Gravity
- Mathematical Physics
- Physics Education
- Epistemology and Philosophy

The morning is devoted to the plenary session, with talks for large audience of physicists in its first half (9h00–10h30), and more specialized in its second half (11h00–12h30); this part is held in three amphitheaters. The parallel session of the Symposium takes place during the afternoon (14h30–18h30) with seven thematic conferences and an additional one on open topics named “Frontiers of Fundamental Physics”. These conferences have been organized around the contributions of participants, in addition of the ones of invited speakers.

B.G. Sidharth (B.M.Birla Science Centre) — Convenor

Updated on January 8, 2015
Scope of the Symposium

These last years have culminated in major results in fundamental physics, and in particular the discovery of the Higgs boson and the measurement of the fluctuations of the blackbody spectrum temperature of the Cosmic Microwave Background. The first one reinforces the standard model of elementary particle physics and the second one provides a basis to the inflation scenario and the quantum origin of cosmological fluctuations, the seeds required for the formation of cosmological structures, and favours a non-zero cosmological constant or/and the alternatives named Dark Energy.

While describing phenomena at extremely large scale for the one and extremely small scale for the other one, the advances in these fields of physics, spawn us a common path to go deeper and deeper in the understanding of fundamental laws. The next steps to accomplish are the correct extension of the Standard Model of particle physics above the electroweak scale, the identification of the Dark Matter and of the Dark Energy, the quantum description of gravity, as well as the development of new mathematical structures related to these questions.

These issues will be jointly discussed in the plenary parts of the Symposium, while recent developments and ongoing researches will be debated on dedicated conferences, whose aims are more precisely described on their own web pages. The multidisciplinary aspect of the symposium will be kept in an additional conference "Frontiers of Fundamental Physics", whose main topics will be identified all along the submission procedure.

Public lecture

During the Symposium FFP14, a public lecture (in french) will be held on **Tuesday, July 15 at 19h00** at the Campus Saint Charles of the Aix-Marseille University.

---

Les bâtisseurs du ciel : de Copernic à demain

Jean-Pierre Luminet

De Copernic à Einstein en passant par Kepler, Galilée et Newton, une poignée d’hommes exceptionnels ont changé de fond en comble notre façon de voir et de penser le monde. Ces inventeurs de génie furent aussi des personnages hors du commun, à qui nous devons l’image d’un cosmos démesuré, cependant mesurable par l’intelligence et l’imagination créatrice.

De nouvelles révolutions scientifiques dans les sciences de l’espace et de la matière sont en gestation en ce début du XXIᵉ siècle : trous noirs, big bang, matière noire, énergie sombre, unification des forces fondamentales. La différence est qu’elles ne sont plus l’œuvre d’individus isolés, mais le fruit d’un travail collectif.

À lire :
- Les Bâtisseurs du ciel, l’intégrale (J.-C. Lattès, 2010)
- Illuminations : Cosmos et Esthétique (Odile Jacob, 2011)
- Bonnes nouvelles des étoiles (Odile Jacob, 2009)
Scope of the conference

At the boundaries of particle physics, cosmology and astrophysics, the astroparticle physics field is a very active domain of fundamental physics both on experimental and theoretical sides. The field focuses on elementary particles in astrophysical or cosmological contexts and addresses questions like the understanding of the cosmic rays, the dark matter enigma, the matter-antimatter asymmetry of the universe.

If the standard LambdaCDM cosmological model indicate the presence of a large amount of non-baryonic dark matter in the universe, the true nature, the behavior and the precise distribution of this unknown species remain illusive and is one of the major question of modern physics. These dark matter is tracked by multimessenger astronomy and underground experiments.

Furthermore, the cosmic rays are also a long standing but fundamental question and understanding their origin, their sources and their propagation are key issues to fully control the features of the CR spectra.

Modeling and measuring cosmic ray fluxes of different messengers like gammas neutrinos, positrons, antiprotons are determining issues for dark matter identification, as well as for the understanding of violent phenomena like gamma ray bursts and supernovae remnant emissions and their contribution to the cosmic ray spectrum. Moreover those phenomena provide probes of the galactic and extragalactic universe.

The present era brings an precedent level of modelling and precision measurements with experiments (like FERMI, HESS, PAMELA, AMS, ICECUBE, ANTARES, XENON, LUX…) to progress in these interdisciplinary fields.

The purpose of the conference is to bring together scientists of adjoining fields to exchange or confront ideas and results.

Topics

— Dark Matter
— Cosmic Rays
— Astrophysical jets
— Multimessenger and Multiwavelength astronomy
— Galactic and Extragalactic emissions
— Neutrinos
Cosmology

The accelerating universe: spacetime structure and matter structures

Scope of the conference

Dark energy cosmology, the study of the causes and effects of the accelerated expansion of the universe, is the natural crossroad where fundamental physics, astrophysics and particle physics meet. This interdisciplinary character has enormously accelerated the progress of researches in this field, and exciting challenges and breakthroughs are expected in the next decade.

Reveling the finest details of cosmic acceleration, unveiling the effects of dark energy on structure formation and evolution processes, and advancing dark energy studies to the next level of complexity, critically depend on the ability to increase the sensitivity of our instruments, to design efficient observational probes and to remove the potential astrophysical biases that can limit our ultimate understanding of the phenomenon. In the next decade, several major ground- and space-based experiments are expected to take up the challenge by drawing a realistic portrait of this elusive component and by answering fundamental questions such as: what is the physical nature of dark energy? Is it a static component or a dynamical one of the cosmic landscape? Is general relativity the correct theory of gravity on the scales of the Universe? Is the standard cosmological paradigm consistent or are there glimpses of new physics?

The purpose of the conference is to bring together observers, modelers and theorists in order to understand the strengths, weaknesses, and complementarities of current and planned dark energy probes as well as of the theoretical approaches developed to interpret and predict observations.

The aim is to present and discuss the latest research results in the fields, as well as to indicate new paths for future explorations by sharing expertise on the following topics: how to design future observational probes of dark energy and optimize the synergy between them? what are the best observables to characterize dark energy? How best to constrain the values of the fundamental cosmological parameters? What are the most efficient and universal ways to parametrize eventual deviations from the Friedman model and to discriminate among competing theories of modified gravity?

Topics

- Dark Energy - Dark Gravity
- Inflation
- Primordial Non-Gaussianity
- Cosmological parameters
- Cosmic Microwave Background
- Large Scale Structure of the Universe
- Galaxy formation and evolution
- Galaxy clustering
- Gravitational Lensing
- Redshift surveys
High Energy Physics

Beyond the Standard Model, Progress in Lattice QCD, Heavy Ion physics

Scope of the conference

The standard model (SM) of the strong, weak, and electromagnetic interactions gives a complete description of the elementary particles and their interactions, accurately describing present data up to the highest presently available TeV scale energies at the LHC. This success culminated with the 2012 discovery of a Higgs-like boson by the LHC ATLAS and CMS collaborations. However, the SM has serious limitations, and the particle physics community is now confronted with the need to identify the correct extension of the SM above the electroweak scale, allowing for a more natural electroweak symmetry breaking (EWSB).

Indeed, the scalar sector effective potential could be the manifestation of a more fundamental mechanism with a dynamical explanation for the EWSB. The two main scenarios for a more natural EWSB mechanism, addressing the hierarchy and naturalness problems, are either low energy supersymmetry (SUSY) or a TeV scale strongly interacting sector. Also of crucial importance to any BSM scenario are the quark and lepton flavor issues, namely the consistency and possible dynamical explanation of the observed pattern of quark masses and mixing as well as neutrino masses and mixing. The direct searches of SUSY signals at the LHC will continue to be crucial to constrain the many SUSY scenarios presently considered. Alternatively, the precise measurements of all the available Higgs decay modes at the LHC will be crucial to disentangle the many strongly interacting scenarios.

On the other side, the dark matter (DM) problem is still unsolved. There are strong theoretical arguments in favor of a ”particle physics” solution within the previous context beyond the SM. A generic DM particle candidate in these theories is the so-called WIMP (weakly interacting massive particle). Complementarily to direct and indirect detection experiments, the LHC also gives hope that if a DM particle is discovered with parameters accessible to it, it will be possible to place this particle into a coherent particle physics scenario.

The symposium will also aim to discuss recent progress in lattice QCD and, more generally, lattice field theory computations. These play a critical role in our understanding of important nonlinear phenomena, ranging from phase transitions in the early universe and in very dense stars to the binding of quarks and gluons into hadrons and nuclei, or from a possible substructure for the Higgs boson to very small effects that may reveal new fundamental physics in experiments.

Another topics aimed to be addressed is Heavy Ion physics, after the first LHC results from the ALICE collaboration and recent theoretical developments on the status of the quark gluon plasma and the deconfinement transition.

Topics

– Beyond the Standard Model (scenarios, LHC constraints and prospects)
– Supersymmetric Models
– Dynamics of Electroweak Symmetry Breaking
– Quark and Lepton Flavor physics and issues
– Neutrino Physics and Models
– Progress in Lattice QCD (zero and finite temperature)
– Heavy Ion physics
– Dark matter (candidates and models)
Quantum gravity remains one of the major open problems at the foundation of physics. There is not yet a consensus about its solution, but the last years have seen substantial progress both in the direction of the possibility of measurements at the Planck scale and on the theoretical side.

For example, the MAGIC observations of the possible non-trivial dispersion relations for light and the astrophysical analysis of the Crab nebula, for instance, have shown that Planck scale observations are possible, contrary to what generally assumed until a few years ago, and have essentially ruled out some tentative quantum gravity theories predicting certain Lorentz violations at the Planck scale.

On the theoretical side, the proof of the finiteness of the loop gravity amplitudes at all orders and the evidence about their small $\hbar$ limit put the theory on a ground much solid than a few years ago. The calculations of possible quantum gravity signatures on the CMB connects these the theoretical advance to cosmology.

Topics

— Loop Quantum Gravity
— Background-Independent Approaches
— Black Hole Entropy
— Loop Quantum Cosmology
— Twistor theory
Scope of the conference

In the past, fundamental problems in theoretical physics have stimulated profound breakthroughs in mathematics, and the current description of the fundamental interactions of particle physics, as well as the description of the whole Universe, rely heavily on geometric and algebraic mathematical structures: representation theory, gauge theories, Riemannian geometry, operator algebras, invariants, combinatorial algebras...

Some recent research programs in mathematical physics have the ambition to answer some unsolved questions of today’s description of Nature, for instance the search for a theory of the quantum gravity, or the mathematical structure of the standard model (SM) of particle physics...

The new mathematical structures that have emerged so far take their roots in both geometry and algebra, and they make apparent some new structures connecting the two. For instance, new mathematical frameworks for gauge field theories, or new quantization procedures have been recently proposed.

As an illustration, the last thirty years have seen the spectacular development of non-commutative geometry (NCG), whose objective is to propose a mathematical framework in which it is possible to think of geometry in terms of operator algebras. On the mathematical side, NCG has provided some new profound results and has stimulated the construction of new structures, while on the physical side, it proposes to take a fresh look at the mathematics behind the SM.

Moreover, the last decade has witnessed important developments in our understanding of the mathematical structure behind renormalisation in quantum field theory. In particular, these include the construction of combinatorial Hopf algebras underpinning the renormalisation procedure and the realization of gauge symmetries.

Topics

— Quantization: geometric and algebraic methods
— Noncommutative geometry: foundation and applications
— Renormalization: algebraic and analytic aspects
Scope of the conference

Nowadays, scientific research is at the heart of many stakes of local developments, as well as territorial and international ones, and it is found in several strategies. Paradoxically, many scientific domains are deserted by students; they prefer some professionalizing training that could provide them more opportunities in terms of employment after graduation. This disaffection seems going together with a decrease of motivation, even a decrease of student’s academic level in scientific disciplines. In master level courses, it is therefore not unusual to be confronted with important differences between, on the one hand, students’ expectations, sometimes manifested by a lack of interest, low motivation and work which sometimes appears as minimalista possible, and, secondly, the requirements of these courses in knowledge, commitment, or in simply in scientific culture.

Among the issues that student behavior generated in the scientific community, particularly two of them will be discussed in this conference:

1. The organization of studies in the LMD structure modifies significantly the training curriculum of students: reduction of volumes of teachings, sequential organization less recurrent, open choice of very diverse options, etc. Is that correct to think that this evolution creates a gap between the structural organization of university curricula and the methods of knowledge transfer that are perhaps no longer suitable to these new structures?

2. The stakes and motivations of students have strongly evolved in recent years, the social goals of university studies have become as important as the domains studied. Their professional future is a criterion more and more important in choosing training and courses. However, the structure of university training, that goes from the general to the specialized specific area, does not give all the desired goals readability. Is this lack of concordance the cause of the significant drop in motivation for students who do not see very well "what’s the point."

The expected contributions should provide us with some insights, elements of understanding on the impact of changing organizational structures of university education. They should also outline issues to explore new educational organizations to think and build in order to improve the effectiveness of the teaching-learning in higher education in the fields of physical science education.

Topics

- Teaching sciences at University and new pedagogies
- Teaching sciences at the secondary school
- Science education at school
- Promotion of the scientific culture through sciences associations
Epistemology and Philosophy

Scope of the conference

The goal is to discuss the epistemological and ontological status of the various notions, concepts involved in modern physics.

This concerns first the physical theories and models themselves: what is a physical theory? What is a good physical theory? In particular how can we characterize it beyond its possibly multiple mathematical formulations? How to interpret the fact that an unique theory can be described by very different mathematical tools and, more generally, how to answer to the Wigner question about the “unreasonable efficiency of mathematics for physics”?

Also, the relations between distinct theories cannot be reduced to differences of mathematical formulations (since an unique theory may admit different formulations). This suggests two tracks:

1. try to analyze the theories, their differences, and also their evolutions independently of any mathematical formulations. Clearly a task for epistemology and philosophy!

2. search for a mathematical formalism sufficiently general to encompass very different theories (presently formulated with different mathematical tools).

Symplectic geometry, groups and algebras with their generalizations play an important role in that concern. We want to discuss in what extent the theory of category may also be useful. We will show particular interest toward the analysis of the evolution of theories (e.g., from classical to quantum; or from Newtonian to Einsteinian physics), in the light of group or algebra deformations, or of catego-

Weak gravitational lensing

11h30 – 12h00  David Spergel (Princeton)  
The Signature of Low Redshift Large-Scale Structure in the Cosmic Microwave Background

12h00 – 12h30  Luigi Guzzo (INAF - OA Brera)  
Cosmology with Galaxy Redshift Surveys

Plenary Session 2  (broadcast)  
Chairman: Laurent Vacavant  
Amphi “Sciences Naturelles”

11h00 – 11h30  Jose W.F Valle (IFIC)  
Neutrino pathways to cosmology

11h30 – 12h00  Fabio Maltoni (CP3)  
The top-quark gateway to new physics

12h00 – 12h30  Francis Halzen (WIPAC)  
IceCube and the Discovery of High-Energy Cosmic Neutrinos

Plenary Session 3  Gravitation and the Quantum  
Chairman: Eugenio Bianchi  
Amphi “Massiani”

11h00 – 11h45  Jorge Pullin (LSU)  
Hawking radiation in loop quantum gravity

11h45 – 12h30  Burra Sidharth (BMBSC)  
A Test Bed for High Energy Physics

12h30 – 14h30  Lunch
July, 16 (cont'd)

14h30 – 16h30  First afternoon parallel sessions

Astroparticle Physics  Neutrinos (common with HEP)
Chairman: Jose W.F Valle  Amphi “Sciences Naturelles”
14h30 – 15h00  Antonio Palazzo (MPI)
  Global status of neutrino oscillations
15h00 – 15h30  Anatael Cabrera (APC)
  Neutrino Oscillations: Experimental Review
15h30 – 16h00  Pasquale Di Bari (UoS)
  Leptogenesis and low energy neutrino data
16h00 – 16h30  Xavier Sarazin (LAL)
  Review of neutrinoless double beta decay search

Cosmology  Theory and Observations of the CMB and LSS
Chairman: Luigi Guzzo  Amphi “Charve”
14h30 – 15h00  Subir Sarkar (UOXF & NBI)
  Galactic foregrounds for the CMB
15h00 – 15h30  Lam Hui (Columbia University)
  Symmetries in Large Scale Structure
15h30 – 15h50  Julien Bel (OAB)
  Probing the matter power spectrum with the galaxy clustering ratio
15h50 – 16h10  Giovanni Marozzi (DPT - Unige)
  The value of \(H_0\) in the inhomogeneous Universe
16h10 – 16h30  Sabir Ramazanov (ULB)
  Probing primordial statistical anisotropy with WMAP and Planck data

High Energy Physics  Neutrinos (common with Astroparticle Physics)
Chairman: Jose W.F Valle  Amphi “Sciences Naturelles”
14h30 – 15h00  Antonio Palazzo (MPI)
  Global status of neutrino oscillations
15h00 – 15h30  Anatael Cabrera (APC)
  Neutrino Oscillations: Experimental Review
15h30 – 16h00  Pasquale Di Bari (UoS)
  Leptogenesis and low energy neutrino data
16h00 – 16h30  Xavier Sarazin (LAL)
  Review of neutrinoless double beta decay search

Quantum Gravity  Loop Quantum Cosmology
Chairman: F. Vidotto  Amphi “Massiani”
14h30 – 15h00  Julien Grain (IAS)
  A brief overview of loop quantum cosmology and its potential observational signatures
15h00 – 15h30  Edward Wilson-Ewing (LSU)
  The Matter Bounce Scenario in Loop Quantum Cosmology
15h30 – 16h00  Jaume Haro (UPC)
  Matter Bounce Scenario in F(T) gravity
16h00 – 16h30  Linda Linsefors (LPSC)
  LQC on curved FLRW space time
Mathematical Physics  Noncommutative Geometry and physical models
Chairman: Pierre Bieliavsky  Room 406
14h30 – 15h15  Ali Chamseddine (AUB and IHES)
Noncommutative Geometry and Physics
15h15 – 16h00  Walter van Suijlekom (RU)
Inner perturbations in noncommutative geometry
16h00 – 16h30  Michal Eckstein (UJ)
Causal structure for noncommutative geometry

Physics Education  New pedagogical approach in Physic Education
Chairman: Valérie Munier  Room 407
14h30 – 15h00  Daniel Rouan (LESIA)
Soon 20 years of “La Main à La Pâte”, an international model for inquiry-based science education in elementary school
15h00 – 15h30  Alexander Rudolph (Cal Poly Pomona)
Introduction of interactive learning into French university physics classrooms
15h30 – 16h00  Marisa Michelini (UniUD)
Teaching modern physics in secondary school
16h00 – 16h30  Nadine Witkowski (UPMC)
Horizons in Physics Education: a network to improve the attraction of physics

Epistemology and Philosophy  Interpretations of Quantum Mechanics
Chairman: Marc Lachièze-Rey  Room 408
14h30 – 15h05  Hervé Zwirn (CNRS / CVT)
Decoherence and the measurement problem
15h05 – 15h40  Philipp Hoehn (PI)
A novel approach to characterising quantum theory based on limited information and complementarity
15h40 – 16h15  Jérôme Rosanvallon (Paris 7)
Quantization, spatiotemporalization and pure variation

Frontiers of Fundamental Physics
Chairman: Burra Sidharth  Room 405
14h30 – 15h00  Valeriy Dvoeglazov (UAZ)
Energy-Momentum Tensor in Electromagnetic Theory and Gravitation from Relativistic Quantum Equations
15h00 – 15h30  Cohl Furey (PI)
Charge Quantization from a Number Operator
15h30 – 16h00  John Williamson (UoG)
A new theory of light and matter
16h00 – 16h30  Joseph Kouneiher (UNS)
Higgs fields, Yang-Mills Quantized theories and the Cohomological origine of the mass

16h30 – 17h00  Coffee break
July, 16 (cont’d)

17h00 – 18h30 Second afternoon parallel sessions

**Astroparticle Physics**  Neutrinos (common with HEP)

Chairman: Jurgen Brunner

Amphi “Sciences Naturelles”

17h00 – 17h30 Paschal Coyle (CPPM)
Mediterranean Neutrino Telescopes

17h30 – 18h00 Cristina Volpe (APC)
Recent advances in neutrino astrophysics

18h00 – 18h30 Eric Baussan (IPHC)
Future of neutrino based reactor experiments

**Cosmology**  Theory and Observations of the CMB and LSS

Chairman: Lam Hui

Amphi “Charve”

17h00 – 17h20 Arnau Pujol (ICE-IEEC/CSIC)
The effects of assembly bias on galaxy clustering predictions

17h20 – 17h40 Agnès Ferté (IAS)
Constraints on chiral gravity through the CMB polarization

17h40 – 18h00 Martín López-Corredoira (IAC)
Tests on the Expansion of the Universe

18h00 – 18h20 Andrei Khmelnitsky (BGU)
Scalar field dark matter and pulsar timing observations

**High Energy Physics**  Neutrinos (common with Astroparticle Physics)

Chairman: Jurgen Brunner

Amphi “Sciences Naturelles”

17h00 – 17h30 Paschal Coyle (CPPM)
Mediterranean Neutrino Telescopes

17h30 – 18h00 Cristina Volpe (APC)
Recent advances in neutrino astrophysics

18h00 – 18h30 Eric Baussan (IPHC)
Future of neutrino based reactor experiments

**Quantum Gravity**  Black-Hole Theory

Chairman: J. Pullin

Amphi “Massiani”

17h00 – 17h30 Frank Saueressig (IMAPP)
Black holes in Asymptotically Safe Gravity

17h30 – 18h00 Alejandro Perez (CPT)
Black hole entropy and entanglement of Planckian degrees of freedom

18h00 – 18h30 Jibril Ben Achour (APC)
Analytical continuation of black hole entropy in Loop Quantum Gravity
July, 16 (cont’d)

Mathematical Physics  Noncommutative Geometry and physical models
Chairman: Paolo Aschieri  Room 406
17h00 – 17h45  Nicola Pinamonti (Univ. of Genova)
  Influence of quantum matter fluctuations on the expansion parameter of timelike geodesics
17h45 – 18h30  Christoph Stephan (UP)
  Model building in almost-commutative geometry

Physics Education  New pedagogical approach in Physic Education
Chairman: Daniel Rouan  Room 407
17h00 – 17h30  Chang-Mo Ryu (POSTECH)
  Design and build physics lab course for general physics program in college
17h30 – 18h00  Damir Buskulic (UdS / LAPP)
  No magic wand for teaching physics

Epistemology and Philosophy  Interpretations of Quantum Mechanics
Chairman: Alexander Afriat  Room 408
17h00 – 17h35  Francesca Vidotto (IMAPP)
  Atomism and Relationalism as guiding principles for Quantum Gravity
17h35 – 18h10  Roman Sverdlov (IISER)
  Describing many-particle QM as well as QFT in terms of “single particle” QM with one extra dimension

Banquet at Palais du Pharo — 19h00
July, 17

09h00 – 10h30  Plenary session

**Plenary Session** (broadcast)
Chairman: Sabino Matarrese  
Amphi “Sciences Naturelles”

09h00 – 09h30  Carlo Rovelli (CPT)  
Loop Quantum Gravity

09h30 – 10h00  Alexei Starobinsky (Landau ITP)  
Investigating inflation and super-high-energy physics with new CMB data

10h00 – 10h30  Vladimir Ptuskin (IPST)  
Origin of Cosmic Rays

10h30 – 11h00  Coffee break

11h00 – 12h30  Morning parallel plenary sessions

**Plenary Session 1**  The primordial universe
Chairman: Alexei Starobinsky  
Amphi “Charve”

11h00 – 11h30  David Wands (ICG)  
Cosmic inflation and primordial structure

11h30 – 12h00  Sabino Matarrese (UNIPD)  
Primordial non-Gaussianity, present status and future prospects

12h00 – 12h30  Jérôme Martin (IAP)  
Inflation after Planck & BICEP2

**Plenary Session 2**
Chairman: Laurent Lellouch  
Amphi “Massiani”

11h00 – 11h30  Christian Hoelbling (Bergische Universität Wuppertal)  
Physical predictions from lattice QCD

11h30 – 12h00  Elena Amato (INAF)  
Particle acceleration in astrophysical sources

12h00 – 12h30  Federico Mescia (UB)  
Review of Flavour Physics

**Plenary Session 3** (broadcast)
Chairman: Carlo Rovelli  
Amphi “Sciences Naturelles”

11h00 – 11h45  Jerzy Lewandowski (UW)  
Background independence of GR and in LQG

11h45 – 12h30  Bernard Whiting (UF)  
High precision gravitational self-force calculations and post-Newtonian implications

12h30 – 14h30  Lunch
July, 17 (cont’d)

14h30 – 16h30  First afternoon parallel sessions

**Astroparticle Physics**  Galactic emissions
Chairman: Guy Pelletier  Amphi “Charve”

14h30 – 15h00  Yasunobu Uchiyama (Rikkyo Univ.)
High Energy and Very High Energy Gamma-rays from Galactic Particle Accelerators

15h00 – 15h30  Alexandre Marcowith (LUPM)
Cosmic Ray propagation in the interstellar medium

15h30 – 16h00  Andrea Goldwurm (APC)
High Energy Phenomena at the Center of our Galaxy

16h00 – 16h30  Elena Amato (INAF)
Particle Acceleration and Radiation in Pulsar Wind Nebulae

**Cosmology**  Physics of the Early Universe
Chairman: Brahim Lamine  Amphi “Sciences Naturelles”

14h30 – 15h00  Leonardo Senatore (Stanford)
Inflation Physics from the CMB and LSS

15h00 – 15h20  Yuko Urakawa (Nagoya)
Infrared physics in inflation and primordial perturbations

15h20 – 15h40  Inyong Cho (SeoulTech)
Inflationary perturbations in Eddington-inspired Born-Infeld gravity

15h40 – 16h00  Chiara Caprini (IPhT)
Magnetic field generation during inflation

16h00 – 16h20  Antonino Marciano (Fudan)
Matter-Bounce Spin-Cosmology and consistency with BICEP2 data

**High Energy Physics**  Higgs measurement and BSM
Chairman: Cyril Hugonie  Amphi “Massiani”

14h30 – 15h00  Jérémie Quevillon (LPT Orsay)
Constraints on BSM physics through the Higgs couplings

15h00 – 15h30  Christopher Neu (UVa)
Search for tH in Run 1 at the LHC

15h30 – 16h00  Wolfgang Mader (IKTP)
Searches for BSM Higgs bosons at LHC

16h00 – 16h30  Nikolas Kauer (RHUL)
Off-shell Higgs signal and total width determination at the LHC

**Quantum Gravity**  Renormalization
Chairman: S. Alexandrov  Room 404

14h30 – 15h00  Daniele Oriti (AEI)
A quantum field theory for the atoms of space

15h00 – 15h30  Johannes Thürigen (AEI)
Group field theories generating polyhedral complexes

15h30 – 16h00  Benjamin Bahr (UH)
On background-independent renormalization in spin foam models

16h00 – 16h30  Seramika Ari Wahyoedi (CPT)
How many quanta are there in a quantum spacetime?
July, 17 (cont’d)

**Mathematical Physics**  (New) Geometry and Quantization

Chairman: Christian Brouder  Room 406

14h30 – 15h15  Pierre Bieliavsky (UCLouvain)
   On Drinfel’d twists and their use in non-commutative geometry

15h15 – 15h45  Jean-Philippe Michel (ULg)
   Higher Symmetries of Laplace and Dirac operators - towards supersymmetries

15h45 – 16h30  Patrick Iglesias-Zemmour (I2M, CNRS)
   Symplectic Diffeology and Moment Maps

**Physics Education**  New pedagogical approach in Physic Education

Chairman: Marisa Michelini  Room 407

14h30 – 15h00  Valérie Munier (UM2)
   Learning physics : from the nature and origins of difficulties to an evolution of teaching

15h00 – 16h30  Guillaume Trap (Palais de la découverte)
   Frontiers of popular physics demonstrations

16h00 – 16h30  Ricardo Coelho (FCUL)
   History and Philosophy of Science Can Improve Problem-Solving

**Epistemology and Philosophy**  Logic and Ontology of Physics

Chairman: Jean-Pierre Luminet  Room 408

14h30 – 15h05  John Stachel (CES)
   Do Quanta Need a New Logic?

15h05 – 15h40  Jean-Jacques Szczeciniarz (Paris Diderot)
   Category and Physics

15h40 – 16h15  Paolo Bertozzini (Thammasat Univ.)
   Categorical Operator Algebraic Foundations of Relational Quantum Theory

**Frontiers of Fundamental Physics**

Chairman: Roland Triay  Room 405

14h30 – 15h00  Marc Lachièze-Rey (APC)
   Dynamics of histories

15h00 – 15h30  Mikhail Altaisky (IKI)
   Continuous wavelet transform in quantum field theory

15h30 – 16h00  Alessandro Bisio (UNIPV)
   From Quantum Cellular Automata to Quantum Field Theory

16h00 – 16h30  Igor Bulyzhenkov (MIPT)
   Field and Matter or Pure Field Physics?

16h30 – 17h00  Coffee break
July, 17 (cont’d)

17h00 – 18h30  Second afternoon parallel sessions

**Astroparticle Physics**  Galactic emissions

*Chairman: Elena Amato*  
*Amphi “Charve”*

17h00 – 17h20  **John Carr** (CPPM)  
The new Gamma Ray Telescope Observatory: CTA

17h20 – 17h40  **Samia Drappeau** (IRAP)  
A new multiwavelength lepto-hadronic model of astrophysical jet emission

17h40 – 18h00  **Thomas Tavernier** (APC)  
Bright Gamma-ray Pulsars in the Fermi Era : Results and prospects with ground-based telescopes

18h00 – 18h20  **Vera Yurievna Sinitsyna** (FIAN RAS)  
Long-term studies of the Cygnus Region and its objects

**Cosmology**  Physics of the Early Universe

*Chairman: Filippo Vernizzi*  
*Amphi “Sciences Naturelles”*

17h00 – 17h30  **Amanda Weltman** (UCT)  
Chameleon Cosmology Near and Far

17h30 – 17h50  **Vladimir Dzhunushaliev** (KazNU)  
Gravitational waves attenuation in a non-perturbative spinorial vacuum

17h50 – 18h10  **Sandrine Schlögel** (UNamur)  
Particle like solutions in modified gravity: the Higgs monopoles

**High Energy Physics**  Higgs measurement and BSM

*Chairman: Sara Diglio*  
*Amphi “Massiani”*

17h00 – 17h30  **Heidi Rzehak** (Uni Freiburg)  
SUSY after LHC run 1

17h30 – 18h00  **Sabine Crépé-Renaudin** (LPSC)  
Searches for heavy resonances at the LHC

**Quantum Gravity**  Renormalization

*Chairman: F. Saueressig*  
*Room 404*

17h00 – 17h30  **Daniel Litim** (US)  
Do interacting ultraviolet fixed point exist, and if so, what can we do with them?

17h30 – 18h00  **Reiko Toriumi** (CPT Marseille)  
Cosmological constant: its identification as renormalization group invariant scale corresponding to a gravitational condensate

18h00 – 18h30  **Tatyana Shestakova** (SFEDU)  
The role of BRST charge as a generator of gauge transformations in quantization of gauge theories and Gravity
Mathematical Physics  Noncommutative Geometry
Chairman: Francesco D’Andrea  Room 406
17h00 – 17h45  Paolo Aschieri (UPO)
   Deformation quantization of Noncommutative Principal Bundles
17h45 – 18h15  Guo Chuan Thiang (Univ. of Oxford, Math. Institute)
   On the K-theoretic classification of topological phases of matter

Physics Education  New pedagogical approach in Physic Education
Chairman: Damien Givry  Room 407
17h00 – 17h30  Alberto Stefanel (UNIUD)
   Upper secondary students face optic diffraction using simple experiments and on-line
   measurements
17h30 – 18h00  Jean-Marc Virey (CPT)
   Experimentation of a new pedagogical method in 1st year’s teachings of physics

Epistemology and Philosophy
Chairman: Julien Bernard  Room 408
17h00 – 17h35  Andrei Rodin (IPRAS)
   Constructive Identities for Physics

Cocktail at the City Hall — 19h00
July, 18

09h00 – 10h30  Plenary session

Plenary Session (broadcast)  
Chairman: Roland Triay  
Amphi “Sciences Naturelles”

09h00 – 09h30  Laurence Viennot (SPC & LDAR)  
Co-development of conceptual understanding and critical attitude: an essential condition for physics learning

09h30 – 10h00  John Stachel (CES)  
It Ain’t Necessarily So: Interpretations and Misinterpretations of Quantum Theory

10h00 – 10h30  Joe Silk (IAP)  
Issues in Galaxy Formation 2014

10h30 – 11h00  Coffee break

11h00 – 12h30  Morning parallel plenary sessions

Plenary Session 1  The dark universe (broadcast)  
Chairman: Joe Silk  
Amphi “Sciences Naturelles”

11h00 – 11h30  Philippe Brax (IPHT)  
Dark Energy and Modified Gravity

11h30 – 12h00  Cédric Deffayet (IAP and IHÉS)  
From DGT to dRGT: a review of “massive gravity” theories

12h00 – 12h30  Kazuya Koyama (UoP)  
Cosmological tests of gravity

Plenary Session 2  
Chairman: Arache Djannati-Atai  
Amphi “Massiani”

11h00 – 11h30  Guy Pelletier (IPAG)  
Relativistic outflows from compact objects and generation of Astroparticles

11h30 – 12h00  Jean-Paul Blaizot (IPhT)  
Recent experimental results and theoretical developments in Heavy Ion physics

12h00 – 12h30  Veniamin Berezinsky (GSSI)  
UHECR: Progress and Problems

12h30 – 14h30  Lunch
### First afternoon parallel sessions

#### Astroparticle Physics  
**Extragalactic emissions**  
Chairman: Veniamin Berezinsky  
Amphi “Charve”

</table>
Mathematical Physics  QFT and Renormalization
Chairman: Ali Chamseddine  Room 406

14h30 – 15h15  Raimar Wulkenhaar (WWU)
Construction of a quantum field theory in four dimensions

15h15 – 16h00  Kasia Rejzner (York)
Perturbative algebraic QFT as a universal framework for constructing physically
motivated models in quantum field theory

16h00 – 16h30  Sylvain Carrozza (CPT)
Renormalization in Tensorial Group Field Theories

Physics Education  New pedagogical approach in Physic Education
Chairman: Valérie Munier  Room 407

14h30 – 15h00  Laurence Viennot (SPC & LDAR)
From a subtractive to multiplicative approach, two concept-driven interactive pathways
on the selective absorption of light

15h00 – 15h30  Benjamin Couturier (CERN)
LHCb outreach activities (on behalf of the LHCb Collaboration)

15h30 – 16h00  Olivier Morizot (AMU)
Collaborating with Historians of Sciences for a deep and complex rewriting of Physics
courses.

16h00 – 16h30  Damien Givry (AMU)
Schema or not schema? that could be the question of teacher

Epistemology and Philosophy  Symmetry and Gödel’s thoughts on Physics
Chairman: Hervé Zwirn  Room 408

14h30 – 15h05  Amilcar de Queiroz (IF-UnB & DFTUZ)
Symmetry, Physical Theories and Theory Change

15h05 – 15h40  Gabriella Crocco (CEPERC)
Kurt Gödel philospher: from logic to epistemology

15h40 – 16h15  Eric Audureau (CEPERC)
Kurt Gödel’s theory of gravitation

Frontiers of Fundamental Physics
Chairman: Bernard Whiting  Room 405

14h30 – 15h00  Alain Blanchard (IRAP)
The cosmological constant and quantum vacuum

15h00 – 15h30  Remo Garattini (UniBg)
Distorting General Relativity: Gravity’s Rainbow and f(R) theories at work

15h30 – 16h00  Zbigniew Haba (ITFWroc)
A fluid of diffusing particles and its cosmological behaviour

16h30 – 17h00  Coffee break
July, 18 (cont’d)

17h00 – 18h30  Second afternoon parallel sessions

**Astroparticle Physics**  Extragalactic emissions
Chairman: Vincent Bertin  Amphi “Charve”

17h00 – 17h20  Aurore Mathieu (CPPM)
   Multi-Messenger analysis with the ANTARES High Energy Neutrino Telescope

17h20 – 17h40  Chang-Mo Ryu (POSTECH)
   Magnetic field generated by the Weibel instability

17h40 – 18h00  Vera Georgieva Sinitsyna (FIAN RAS)
   Very high energy gamma-emission of Perseus Cluster

**Cosmology**  Dark energy and Dark gravity
Chairman: Cédric Deffayet  Amphi “Sciences Naturelles”

17h00 – 17h30  Filippo Vernizzi (IPhT, CEA Saclay)
   Healthy theories beyond Horndeski

17h30 – 17h50  Lasma Alberte (BGU)
   Massive Gravity with Two Stückelberg Fields

17h50 – 18h10  Chang-Young Ee (Sejong Univ.)
   Friedmann equation and the emergence of cosmic space

18h10 – 18h30  Plamen Fiziev (JINR)
   Dark Energy and Dark Matter in Stars Physic

**High Energy Physics**  QCD, Heavy Flavors and Heavy Ions
Chairman: Jérôme Charles  Amphi “Massiani”

17h00 – 17h30  Kalman Szabo (ISC-JSC)
   Recent progress in Lattice QCD thermodynamics

17h30 – 18h00  Diego Stocco (Subatech)
   ALICE results in p–Pb collisions at the LHC

**Quantum Gravity**  Canonical Quantization
Chairman: H. Haggard  Room 404

Gravitational Scattering via Twistor Theory

Scattering amplitudes are among the most natural--and important--observables of any field theory in an asymptotically flat space-time, including any theory of quantum gravity. Recently, gravitational scattering amplitudes have been shown to possess remarkably compact expressions which are un-expected from the perspective of traditional Lagrangian-based perturbation theory (c.f., [1]). We will discuss how some of these formulae arise from working with an action principal not on space-time, but rather in twistor space, an auxiliary complex three-manifold [2]. This narrative exploits an on-shell equivalence between conformal gravity and general relativity in asymptotically de Sitter manifolds [3], and also leads to new expressions for analogues of scattering amplitudes in space-times with a positive cosmological constant.

Weyl’s gauge argument

The standard U(1) “gauge principle” or “gauge argument” produces an exact potential $\Lambda = d\Lambda$ and a vanishing field $F = d^2 \Lambda$. Weyl [1,2] has his own gauge argument, which is sketchy, archaic and hard to follow; but at least it produces a curved potential $\Lambda$ and nonvanishing field $F = dA$. I attempt a reconstruction.

Arrival direction distribution of cosmic rays from 100 PeV to the highest energies detected at the Pierre Auger Observatory

At the Pierre Auger Observatory, several searches for anisotropies in the distribution of arrival directions of cosmic rays detected above 100 PeV are undertaken. Although no significant deviation from isotropy is revealed at present, some measurements related to the angular distributions at large scales are suggestive of dipole patterns of small amplitudes over a wide energy range. Upper limits on the dipole and quadrupole moments derived from these analyses constrain scenarios in which cosmic rays could originate from stationary Galactic sources emitting in all directions up to the ankle energy. This is supported by the absence of any detectable point-like sources above 1 EeV that would be indicative of a neutron flux. At ultra-high energies, searches for correlations of cosmic rays with populations of nearby extragalactic objects are also presented.

Massive Gravity with Two Stückelberg Fields

We consider non-linear massive gravity with two Stückelberg fields [1]. In this case we find the analytic expression for the determinant of the kinetic matrix of the scalar field Lagrangian and perform the full constraint analysis. This theory admits a charged anti-de Sitter black brane solution and has recently been used in holographic context as a bulk description of a boundary field theory with momentum dissipation [2,3]. We derive the previous results for the holographic conductivity in a coordinate independent way.

First order gravity on the light front

After a brief review of unusual features of the light front canonical formulations of field theories, I present the analysis of the canonical structure of the first order formulation of general relativity on a lightlike foliation. It appears to be quite different from the usual spacelike case leading, for instance, to the presence of tertiary constraints. Besides, I discuss the issue of the zero modes and argue that there might be some hidden correspondence with two-dimensional theories.

Altaisky Mikhail (IKI)  

Continuous wavelet transform in quantum field theory

We describe the application of the continuous wavelet transform to calculation of the Green functions in quantum field theory: scalar $\phi^4$ theory, quantum electrodynamics, quantum chromodynamics. The method of continuous wavelet transform in quantum field theory presented in [1,2] consists in substitution of the local fields $\phi(x)$ by those dependent on both the position $x$ and the resolution $a$. The substitution of the action $S[\phi(x)]$ by the action $S[\phi_a(x)]$ makes the local theory into nonlocal one, and implies the causality conditions related to the scale $a$, the region causality [2]. These conditions make the Green functions $G(x_1, a_1, \ldots, x_n, a_n) = \langle \phi_{a_1}(x_1) \ldots \phi_{a_n}(x_n) \rangle$ finite for any given set of regions by means of an effective cutoff scale $A = \min(a_1, \ldots, a_n)$.

Particle Acceleration and Radiation in Pulsar Wind Nebulae

Pulsar Wind Nebulae are the astrophysical sources that host the most relativistic shocks in Nature and the only Galactic sources in which we have direct evidence of PeV particles. These facts make them an ideal laboratory for High Energy Astrophysics and the ideal place where fundamental processes common to different classes of relativistic sources can be understood.

I will review the current status of our theoretical understanding of Pulsar Wind Nebulae. In recent years, axisymmetric models of pulsar winds with a latitude dependent energy flux have proved very successful at explaining the high energy morphology of PWNe. This success has prompted developments aimed at using multi-wavelength observations of these nebulae as a diagnostics of the hidden physics of the pulsar wind and of the mechanism(s) through which particles are accelerated at the highly relativistic shock that terminates the wind.

I will discuss these most recent developments in terms of the information that we infer from detailed comparison of simulated synchrotron and inverse Compton emission with current observations.
Amato Elena (INAF)  

July, 17, 11h30 – 12h00, Amphi “Massiani”, Plenary Session 2

Particle acceleration in astrophysical sources

Astrophysical sources are extremely efficient accelerators. Some sources emit photons up to multi-TeV energies, a signature of the presence, within them, of particles with energies much higher than those achievable with the largest accelerators on Earth. Even more compelling evidence comes from the study of Cosmic Rays, charged relativistic particles that reach the Earth with incredibly high energies: at the highest energy end of their spectrum, these subatomic particles are carrying a macroscopic energy, up to a few Joules.

Here I will address the best candidate sources and mechanisms as cosmic particle accelerators. I will mainly focus on Galactic sources such as Supernova Remnants and Pulsar Wind Nebulae, which being close and bright, are the best studied and understood among astrophysical accelerators. These sources are probably responsible only for particle acceleration up to PeV energies, and hence for most of the energy that is put into relativistic particles in the Universe, but not for the highest individual particle energies. However they allow us to study in great detail acceleration mechanisms such as shock acceleration (both in the newtonian and relativistic regime) or magnetic reconnection, the same processes that are likely to be operating also in more powerful sources.

How many quanta are there in a quantum spacetime?

We develop a technique for describing quantum states of the gravitational field in terms of coarse grained spin networks, following earlier insights by Livine and Terno [1], [2]. This technique shows that the number of nodes and links in a quantum state of gravity, and the spin associated to the links, depend on the observables chosen for the description of the state, and therefore the question of the title is ill posed, unless further information about what is been precisely measured is given.

Deformation quantization of Noncommutative Principal Bundles

Drinfeld twist deformation theory of modules and algebras that carry a representation of a Hopf Algebra $H$ can be extended to deform also morphisms and connections that are not $H$-equivariant. In this talk I present how similar techniques allow to canonically deform principal $G$-bundles, and in general how Hopf-Galois extensions are canonically deformed to new Hopf-Galois extensions.

Twisting the structure group we obtain principal bundles with noncommutative fiber and where the structure group is a quantum group. Twisting the automorphism group of the principal bundle we further obtain a noncommutative base space.

Distances to supernovae: an efficient probe of dark energy

Measuring distances to supernovae (or more precisely to the “type Ia” subclass) has allowed us to measure the distance-redshift relation beyond linear order for the first time in 1998. These first results already showed strong evidence for an accelerated cosmological expansion at the present epoch. This has been confirmed by several other cosmological probes, but what causes this accelerated expansion remains elusive. Our ignorance is commonly parametrized using the “equation of state of dark energy”, where dark energy refers to the fluid one can postulate to source the acceleration. I will present how supernova measurements have evolved since the discovery, review the latest dark energy constraints, and discuss the future of the probe.
Kurt Gödel’s theory of gravitation

Gödel’s contribution to GR [1] have been criticized by several first rank physicists like Chandrasekhar, R.Ellis, S.Hawking, R.Penrose, J.Wheeler [2]. These criticisms (lack of physical meaning, violation of causality,...) contrast with Gödel own description of his work: “[It] relates to the pure theory of gravitation published in 1916 which, I believe, was left, not only by Einstein himself but also by the whole generation of contemporary physicists, in its state of a torso, physically, mathematically, and with respect to its application in cosmology.” I will, in first place, explain why recurrent criticisms addressed to Gödel’s exact solutions of Einstein’s field equations are unjustified. In second place, I will illustrate in what sense Gödel’s contributions to GR is what Einstein tried to do in 1917, namely a completion of the theory of gravitation.

References

On background-independent renormalization in spin foam models

In recent years, spin foam models have been proposed to define a path integral for quantum gravity in a non-perturbative and background-independent way. In this talk I will address the questions of continuum limit and diffeomorphism symmetry in these models, and relate them to the notion of Wilsonian renormalization group flow. A proposal for a background-independent formulation of renormalization for spin foam models will be presented, which does not require a notion of length scale. The concept of cylindrical consistency plays a crucial role in this context, and we show how it naturally defines the RG equations, providing a continuum limit for the theory.

Dynamics of pedagogical innovations: roots and developments. Cases of study in Physics and Mathematic

In general, education, R&D and working life cooperation should form a solid and interactive whole that is able to respond to dynamic and ever-changing expectations. Embedding pedagogical knowledge in innovation activities may offer a long-desired theoretical basis for developing knowledge-based competitiveness in the cooperation between working life and education. Here, the cornerstones of innovation pedagogy are interdisciplinary operations, R&D, curricula and internationalisation in addition to entrepreneurship and service activities.

The key elements here are innovative learning and teaching methods, which can be interlinked with the surrounding working life and innovations by physical products, services and processes. Acting together in an interrelated, interactive and innovative environment, these elements operate within the circle of continuous improvement. In such settings, learning and teaching methods are developed more expeditiously, working life operations and competitiveness are enhanced and new innovations are created.

The overall aim of innovation pedagogy is to contribute to the development of student’s innovation competencies. Innovation competencies refer to knowledge, skills and attitudes needed for the innovation activities to be successful.

Future of neutrino based reactor experiments

The last angle of the PMNS mixing matrix has been measured by the neutrino reactor experiments. This important result opens the door to the precision era in the neutrino oscillation landscape. In this context, the next generation of reactor experiments at the kiloton scale will significantly improve the measurements on the oscillation parameters and will give an answer on the mass hierarchy in the next decades. After a brief summary of the last results, these experiments will be presented with their technological challenges to reach the required sensitivity.

Probing the galaxy clustering ratio with the galaxy clustering ratio

The galaxy clustering ratio [1,2] is a new clustering statistic that provides access to characteristic parameters of the power spectrum of mass density fluctuations without the need to specify the galaxy biasing function nor a model for peculiar velocity distortions. I will demonstrate the method using galaxy simulations as well as real redshift data (from the VIPERS and the SDSS surveys) and show that it allows to fix the reduced density of matter to a precision of nearly 6%. I will argue that this approach will be instrumental in searching for evidences of new physics beyond the standard model of cosmology and in planning future redshift surveys such as EUCLID.

Analytical continuation of black hole entropy in Loop Quantum Gravity

Recovering the Bekenstein-Hawking formula for black hole entropy is a crucial test for any candidate to a quantum theory of gravity. The approach followed in Loop Quantum Gravity leads successfully to the famous formula, up to a choice for the real Barbero-Immirzi parameter, plus logarithmic corrections in agreement with other approaches. However, it has been recently shown in [1] that proceeding to an analytic continuation of the dimension of the Hilbert space of the Chern Simons theory (related to the degrees of freedom of the horizon) leads directly to the exact Bekenstein Hawking formula (without recovering the logarithmic corrections). Therefore, working with the self dual Ashtekar connection seems to give directly the right result. Such a result underlies the status of the complex Ashtekar variables as the good connection to use in Loop Quantum Gravity, additional works pointing in the same direction [2] [3] [4] [5] [6]. Yet, a rigorous construction of this analytical continuation was still missing. This is precisely what was done in a recent article and this is the subject of this talk. I will first focus on the construction of the analytical continuation. Then, I will detail the main result, that is the Bekenstein-Hawking formula and its logarithmic corrections in the context of Self Dual Loop Quantum Gravity.

UHECR: Progress and Problems

Three fundamental problems in the field of UHE astrophysical particles are reviewed.

UHE particles are observed at energies higher than $1 \times 10^{20}$eV, with $3 \times 10^{20}$eV as the highest energy. In principle, in cosmology there are the reliable mechanisms of particle production with energies much higher than $10^{20}$eV (e.g. Topological Defects or Super Heavy Dark Matter), but this production most probably cannot explain the observational data. It is widely argued nowadays that traditional acceleration, e.g. acceleration by relativistic shocks, cannot provide the observed highest energies.

The other fundamental problem is propagation of protons and nuclei in extragalactic space. This problem is studied thoroughly theoretically with prediction of spectral features, dip and GZK cutoff, for protons, which are observed in data of HiRes and Telescope Array, but contradict to mass composition measured by of Auger.

The third fundamental problem is cosmogenic neutrinos, produced by interaction of UHE protons and nuclei with background radiation CMB and EBL. Neutrinos detected by IceCube in 2010 - 2012 do not correspond to standard predictions, and detection of cosmogenic neutrinos probably expects the future space detector JEM-EUSO.

Categorical Operator Algebraic Foundations of Relational Quantum Theory

We provide an algebraic formulation of C.Rovelli’s relational quantum theory [1] that is based on suitable notions of “non-commutative” higher operator categories, originally developed in the study of categorical non-commutative geometry [2,3,4].

As a way to implement C.Rovelli’s original intuition on the relational origin of space-time [5], in the context of our proposed algebraic approach to quantum gravity via Tomita-Takesaki modular theory [6], we tentatively suggest to use this categorical formalism in order to spectrally reconstruct non-commutative relational space-time geometries from categories of correlation bimodules between operator algebras of observables.

Causality and Noncommutative Geometry

Motivated by the introduction of causality in noncommutative geometry, we define the notion of isocone. An isocone is a closed convex cone in a C*-algebra, containing the unit, which separates the states and is stable by non-decreasing continuous functional calculus.

We show that our definition is physically well-motivated, and corresponds exactly to the structure of non-decreasing real functions on a (compact) topological ordered set satisfying a natural compatibility condition between the topology and the partial order, when the C*-algebra is commutative [1].

We also give the complete classification of isocones in finite dimensional algebras, corresponding to finite noncommutative ordered spaces, and give some examples in infinite dimension [2].

Finally we show that the existence of an isocone on an almost commutative algebra C(M) ⊗ A_F of the kind which appears in the NCG formulation of the Standard Model forces the causal order relation on M to disappear in the neighbourhood of every point [3]. Although the scale at which causality disappears is left unspecified by this very general mathematical result, it only depends on the noncommutativity of the algebra A_F, hence on particle physics, and might thus be expected to be much larger than the Planck scale and to possibly leave an observable imprint on the cosmic microwave background.

On Drinfel’d twists and their use in non-commutative geometry

I will present some recent developments in the theory of non-formal Drinfel’d twists. A Drinfel’d twist consists in a tool that allows to deform in an associative way any associative algebra that possesses a given symmetry. For instance the Moyal twist is a Drinfel’d twist for the abelian symmetry R^n. I will report a general method for constructing Drinfel’d twists based on generally non-abelian symmetries. I will conclude by mentioning applications in various domains.

July, 17, 15h30 – 16h00, Room 405, Frontiers of Fundamental Physics

From Quantum Cellular Automata to Quantum Field Theory

This talk is based on Refs. [1,2,3]. We explore the idea that Quantum Field Theory could be grounded on a Quantum Cellular Automaton (QCA) model (i.e. a discrete unitary evolution of a lattice of quantum systems). In the $1+1$-dimensional case, we show that the translation, parity and time-reversal symmetries lead to QCA model which recovers 1D Dirac field equation in the large scale limit. The discreteness of this model implies a breakdown of Lorentz covariance, which is replaced by a doubly special relativity model with an invariant length. Finally we will discuss the phenomenology of the QCA model and extensions to the three dimensional and interacting cases.

Recent experimental results and theoretical developments in Heavy Ion physics

Ultra-relativistic heavy ion collisions allow us to study the densest and hottest forms of matter that can be created in the laboratory, states of matter that have existed in the early universe for only a brief instant, a few microseconds after the big bang.

In this talk, I shall present a short overview of the latest developments in the field, by choosing a few highlights from the results obtained at the LHC. I shall also discuss the evolution of ideas and concepts that have been triggered by these experiments.

Blanchard Alain (IRAP)  
July, 15, 17h00 – 17h30, Amphi “Sciences Naturelles”, Cosmology

Clusters for Cosmology

The properties of clusters are known to provide critical information of cosmological relevance. I will discussed the various observational probes on clusters and how physical models of clusters can be build based on simple scaling laws. I will show how the standard predictions of these models within the concordance picture conflict with present day observations, leading to the cluster conundrum: $x$-ray temperature distribution of clusters at different redshift conflicts with standard scaling expectations, SZ clusters counts as obtained by PLANCK lead to cosmological parameters in tension with those obtained from the CMB fluctuations. Solutions to evade this problem will be discussed as well as ways to progress on this issue.

July, 18, 14h30 – 15h00, Room 405, Frontiers of Fundamental Physics

The cosmological constant and quantum vacuum

The acceleration of the expansion can now be regarded as established beyond reasonable doubt. However, the physical origin of this acceleration, the so-called dark energy, remains a puzzling problem in fundamental physics. The current explanations, quintessence and modified gravity, are based on a fundamental revision of known physics.

Here I will present a revival of an old proposition: that the origin of cosmic acceleration is due to the gravitational active vacuum.

Blondel Alain (DPNC University of Geneva)

Cosmological results from Planck and LSS

Sketched out in 1992, selected by ESA in 1996, launched in 2009, Planck delivered on March 21st its first full sky maps of the millimetric emission at 9 frequencies, as well as those which follow from them, and in particular Planck map of the anisotropies of the Cosmic Microwave Background (CMB). The later displays miniscule variations as a function of the observing direction of the temperature of the fossil radiation around its mean temperature of 2.725K. I will briefly describe how these high resolution maps with a precision of a few parts in a million have been obtained, from collection to analysis of the first 500 billion samples of our HFI instrument.

CMB anisotropies reveal the imprint of the primordial fluctuations which initiate the growth of the large scale structures of the Universe, as transformed by their evolution, in particular during the first 370 000 years, i.e. till the Universe became transparent and the forming of the image we record today. The statistical characteristics of these anisotropies allow constraining jointly the physics of the creation of the primordial fluctuations and that of their evolution. They teach us the possible value of the parameters of the models which we confront to data. I will describe Planck estimates of the density of the constituents of the Universe (usual matter, cold dark matter or CDM, dark energy,...), and their implication in terms of derived quantities like the expansion rate or the spatial curvature. I will review what we learnt on the generation of the fluctuation, and will discuss extensions of the standard cosmological model, so called “Lambda-CDM”, both in term of non minimal physical models – multi-field inflation for instance, or additional constituents - like cosmic strings or a fourth neutrino.

Finally, it will briefly describe other promising results on the matter distribution which is travelled through by the CMB image on its long 13.7 billion years trip towards us. I will mention in particular what we can learn on the dark matter distribution - which is detected through its distorting effect of the CMB image by gravitational lensing, or that of hot gas, which is revealed by the spectral distortion it induces.

July, 15, 15h30 – 16h00, Room 407, Physics Education

Reimagining the teaching of physics in university

In France, the teaching of physics at a university level generally follows the classical pattern lecture / tutorials / students’ labs. Within this framework, we developed in our university new teaching units based on a project approach, following a “learning by doing” philosophy; a one semester unit focusing on outreach project (such as street art as a way to engage a public, a board game to discover astrophysics, and so on), and a week-long setup. The outreach unit has been running for two years; the latter unit will be tested next year. We will present and discuss these units and how they are perceived by the students, who are not used to this approach. We will also present new ways to talk about physics that can be used outside the university to engage a larger public, developed in collaboration with designers, graphic and web professionals (see www.physicsreimagined.com).

Brax Philippe (IPHT)  

July, 18, 11h00 – 11h30, Amphi "Sciences Naturelles", Plenary Session 1

Dark Energy and Modified Gravity

I will review some of the recently uncovered connections between dark energy and modified gravity. Dark energy involves light scalar fields which would naturally lead to deviations from Newton’s law in the solar system. Those are extremely constrained by gravity tests. I will present how one can reconcile dark energy on large cosmological scales with gravity as tested in the solar systems. For that, I will introduce screened modified gravity models and discuss their properties.

July, 15, 15h15 – 16h00, Room 406, Mathematical Physics

Noncommutative version of Borcherds’ approach to quantum field theory

Richard Borcherds recently proposed [1] an elegant geometric version of renormalized perturbative quantum field theory in curved spacetimes, where Lagrangians are sections of a Hopf algebra bundle over a smooth manifold. Borcherds’ framework provides an algebraic interpretation of causal perturbation theory (Stueckelberg, Bogoliubov, Epstein, Glaser,...). We present a noncommutative version of Borcherds approach. Although the normal product is now the tensor product, this version can still be equivalent to standard quantum field theory if the Hopf algebra fiber is graded cocommutative [2]. The relation with almost-commutative geometry [3] is discussed.

Exotic hadrons in Experiment and on the Lattice

Although the constituent quark model correctly predicts the quantum numbers of nearly all known hadrons, it fails to account for so-called ‘exotic’ states. After briefly reviewing the current experimental status of some candidate exotic hadrons, I will discuss prospects for elucidation of their properties using numerical Lattice QCD simulations. Recent theoretical advances have greatly improved lattice calculations of hadronic resonances, but some of the most interesting systems (such as exotic charmonium states) remain a challenge.
Field and Matter or Pure Field Physics?

What did Einstein infer by stating [1] “Could we not reject the concept of matter and build a pure field physics? What impresses our senses as matter is really a great concentration of energy into a comparatively small space. We could regard matter as the regions in space where the field is extremely strong. ... A thrown stone is, from this point of view, a changing field, where the states of greatest field intensity travel through space with the velocity of the stone. There would be no place, in our new physics, for both field and matter, field being the only reality.”

One can indeed resolve the classical field equations in terms of infinite radial distributions for elementary masses and electrical charges [2]. Continuous field-type particles are counted by the left-hand side of the Einstein Equation where the Ricci scalar turns out to be geometrized mass density of such a non-empty, material space or inhomogeneous relativistic fluid [3]. Laboratory tests with precise clocks may distinguish in practice non-empty and empty space paradigms.

References

From Kerr-Newman Black Hole to Spinning Particle: Where is There Hidden the Dirac Equation?

The Kerr-Newman black hole solution has many remarkable evidences of its relationships with the structure of the Dirac electron. Extra high spin/mass ratio of the electron corresponds to over-rotating Kerr geometry, singularity of which has to be regulated, forming a soliton-source [1]. There appears principal question: where and how the Dirac equation can be hidden inside the solitonic bag-like source of the Kerr-Newman spinning particle. In this talk we show that soliton represents a domain wall bubble confining the Higgs field in false vacuum state. The Kerr theorem creates two massless spinor fields (Weyl spinors) which interact via Yukawa coupling and turn into Dirac field, acquiring mass term from the Higgs field [3].

Neutrino Oscillations: Experimental Review

The Neutrino Oscillation phenomenon has been fully established manifestation of both the non-trivial mixing in the leptonic sector, characterised by the PMNS (3x3 matrix in the 3 neutrino type scenario) and the non-degenerate mass state spectrum of neutrinos. As a consequence, we know that mixing is part of the phenomenology of both quarks and leptons, including CP violation, although their mixing patterns have so far been measured to be very different and the possible physics behind remains unknown. Evidence for neutrino CP violation has not yet been observed, due to lack of experimental sensitivity. Also, thanks to the observation of neutrino oscillations, neutrinos are known to be massive. The absolute mass value is still unknown, being much lower than all other known fermions. In my talk, I will briefly review the experimental status of our knowledge as of the Neutrino 2014 (June 2014 at Boston, USA) conference. Improvements due to foreseen experiments will be also highlighted.
Magnetic field generation during inflation

Large scale magnetic fields are ubiquitous in the universe: they are observed in galaxies and clusters, even at high redshift, and recently a lower bound on the magnetic field amplitude in the inter-galactic medium has been established using gamma ray telescopes. The origin of cosmological magnetic fields is still unknown, but their presence in the voids among structures points towards a generation in the very early universe. However, there is currently consensus about the absence of a satisfactory model, based on a gauge invariant lagrangian, able to produce during inflation the magnetic fields present in voids. After reviewing the considerations that lead to such conclusion, I will discuss how it is possible to evade them.

The new Gamma Ray Telescope Observatory: CTA

The Cherenkov Telescope Array (CTA) will provide a new ground based gamma ray observatory with sensitivity ten times better than existing gamma ray experiments. CTA will also have a much wider energy range and improved angular resolution.

The presentation will describe the telescope array which is reaching the final stages of design and prototyping. An vital first decision for CTA will be the choice of the sites and the status of this will be given together with the general schedule expected.

The science program will be presented with some focus on the plans for indirect searches for dark matter.

Renormalization in Tensorial Group Field Theories

In this talk, I will review some recent results about the renormalization of Tensorial Group Field Theories. These theories are motivated by an approach to quantum gravity which lies at the crossroad of tensor models and loop quantum gravity. From the mathematical point of view, they are quantum field theories defined on compact Lie groups, with specific non-local interactions. Interestingly, these non-localities can be controlled and several models have now been proven perturbatively well-defined [1, 2, 3, 4, 5, 6]. I will focus on a SU(2) model inspired by Eucliden 3d quantum gravity, which has been proven renormalizable at all orders with up to \( \varphi^6 \) interactions [6]. Time allowing, I will also present new results about the renormalization group flow of this model.

On the Relation Between Gauge and Phase Symmetries

We propose a group-theoretical interpretation of the fact that the transition from classical to quantum mechanics entails a reduction in the number of observables needed to define a physical state (e.g. from q and p to q or p in the simplest case). We argue that, in analogy to gauge theories, such a reduction results from the action of a symmetry group. To do so, we propose a philosophical-oriented analysis of formal tools coming from symplectic geometry and group representation theory, notably Souriau’s moment map, the Marsden-Weinstein symplectic reduction, the symplectic “category” introduced by Weinstein, and the conjecture (proposed by Guillemin and Sternberg) according to which “quantization commutes with reduction”. By considering the case of an abelian Hamiltonian action on a symplectic manifold, we argue that phase invariance in quantum mechanics and gauge invariance have a common geometric underpinning, namely the symplectic reduction formalism. This stance points towards a gauge-theoretical interpretation of Heisenberg indeterminacy principle. We revisit (the extreme cases of) this principle in the light of the difference between the set-theoretic points of a phase space and its category-theoretic symplectic points.

Inflationary perturbations in Eddington-inspired Born-Infeld gravity

We briefly introduce the inflation model driven by a massive scalar field in Eddington-inspired Born-Infeld gravity [1] investigated in [2]. We present the recent results of the tensor perturbation in this model investigated in [3]. For short wave-length modes, the perturbation feature is very similar to that of the usual chaotic inflation. For long wave-length modes, the perturbation exhibits a peculiar rise in the power spectrum which may leave a signature in the cosmic microwave background radiation. We also briefly discuss the scalar perturbation in this model.

History and Philosophy of Science Can Improve Problem-Solving

There has been much research on students’ misunderstandings of force. Some physicists have pointed out, however, that we do not know what force is. The most common definition of force in textbooks - force is the cause of acceleration - has been criticized for more than two centuries (d’Alembert, Carnot, Kirchhoff, Mach, Hertz, Poiccaré, among others). By means of the simple Atwood machine problem it will be shown that the concept of force as cause of acceleration can be misleading [1,2,3]. It can be shown, however, that this concept of force is a logical consequence of the law of inertia. This law, in turn, cannot be tested experimentally (Planck, Schaefer, French, Nolting, among others). To avoid a statement of which we cannot be sure, the present paper proposes to understand the law through its function in the theory. In this case, we do not have to say how a free body moves, but rather that the rectilinear and uniform motion is the motion of reference in Newtonian mechanics. This enables us to overcome that difficulty with the concept of force.

LHCb outreach activities (on behalf of the LHCb Collaboration)

The LHCb experiment is a general purpose spectrometer in the forward region optimized for precision studies of beauty and charm hadron properties. The volumes of data produced by the LHC make it possible to perform such precision measurements with only a fraction of the total LHCb dataset, making it an ideal playground for developing new types of masterclass exercises.

We present here LHCb’s first foray into the masterclass programme, in which students are taught how to make a 1% precision measurement of the D0 meson lifetime. The students learn to separate D0 mesons from the background in LHCb’s vertex detector and build up a signal mass peak, before learning about how to use background sidebands to extract the signal properties in other variables of interest. They then perform a fit to measure the D0 lifetime, and discover that the result is biased by charm produced in the decays of B hadrons, which has an artificially long lifetime compared to charm produced directly in the proton-proton collision. Finally, the students learn how to separate these two kinds of charm based on the D0 mesons distance of closest approach to the primary interaction and obtain a precise measurement in agreement with the world average. We present the software framework developed for this exercise, give a demonstration of the exercise, and discuss plans for the future.

Mediterranean Neutrino Telescopes

ANTARES is a deep sea neutrino telescope located in the deep sea 40km off the southern coast of France. The results of searches for cosmic neutrinos produced in astrophysical sources and from annihilation of dark matter in the Sun and Galactic centre are presented.

The European neutrino astronomy community has recently started the construction of KM3NeT, a several cubic kilometre neutrino telescope. The R&D for this new research infrastructure are described. Finally, the potential for a measurement of the neutrino mass hierarchy, with a densely instrumented detector configuration (ORCA) is discussed.
Kurt Gödel philosopher: from logic to epistemology

Kurt Gödel left Philosophical Remarks in his Nachlass that he himself entitled Max Phil. The opus originally comprised 16 notebooks but one has been lost. The content is on the whole the outline of a rational metaphysics that allows us to relate the different academic disciplines to each other and in particular logic, mathematics, physics, biology and theory of knowledge.

The notion of time is most interesting for Gödel because it is a subject that connects humanities with the sciences. Therefore he engages with it quite often and quite intensely. This is also true for the concept of force. His transdisciplinary approach is to contemplate ‘force’ as a notion in physics (gravitation and quantum mechanics), as a notion in psychology (affects and emotions) and as a notion in biology, albeit he has a specific interest in physics concerning the concept of force. He is looking for an interpretation of the concept that would allow him to align the theories of relativity and quantum mechanics. Besides that the preoccupation with light quantum gives Gödel an opportunity to reflect on the differences between light and matter. We will present the main structure of Max-Phil, which as been partially transcribed and translated by a international team funded by the ANR project BLA -09-13 and focus on some remarks concerning the relationship between mathematics and physics.

Searches for heavy resonances at the LHC

Resonances decaying into a pair of particles are an obvious place to look for phenomena beyond the Standard Model. This talk summarizes recent results from the ATLAS and CMS experiments on searches for resonances in pairs of jets, leptons, bosons or a mix of those objects. Various models are considered from $Z'$ and $W'$ to the ADD large extra dimension scenario, from excited quarks or technicolor to quantum black holes as well as contact interactions. Results from $\sqrt{s} = 8$ TeV are presented.

Observables and anomalies in $B^0 \to K^{*0}\mu^+\mu^-$ decays

Recent angular analyses of $B^0 \to K^{*0}\mu^+\mu^-$ decays at LHCb are in tension with the standard model predictions. Phenomenological interpretations of these results imply hints of a contribution from a new vector particle. These results are difficult to account for within supersymmetric models. This talk will cover the experimental aspects of performing such an angular analysis using the LHCb detector as well as the theoretical motivation for making such a measurement and the rationale behind the choices of observables. I will devote some time to reviewing the phenomenological interpretations.

Vector bundles on the noncommutative torus from cochain quantization

The non-commutative torus is commonly described as a cocycle quantization of the group ($\mathbb{C}^*$-)algebra of the abelian group $\mathbb{Z}^2$. In the first part of the talk I will explain how, using the WBZ transform of solid state physics, finitely generated projective modules over the noncommutative torus can be interpreted as deformations of vector bundles on elliptic curves by the action of a 2-cocycle, provided that the deformation parameter of the NC-torus and the modular parameter of the elliptic curve satisfy a non-trivial relation.

I will then discuss the relation between (formal) deformations of vector bundles on the torus and cochain twists based on the Lie algebra of the 3-dimensional Heisenberg group.

Based on a joint work with G. Fiore and D. Franco.

Gamma-ray bursts

Gamma-ray bursts are the most powerful explosions in the Universe. They appear as brief bursts of gamma-rays followed by an afterglow at longer wavelengths. They involve a complex physics with a relativistic ejection by a new-born compact stellar mass source, and several phases of emission associated to internal dissipation in the ejecta and to the interaction of the ejecta with its environment. I will review the observations of these phenomena and discuss our current understanding of their physical origin.
“CP violation effects in multibody B decays” on behalf of the LHCb Collaboration

CP violation is one of the necessary ingredients to produce the matter anti-matter asymmetry we observe in the Universe today. The LHCb experiment is a general purpose forward-spectrometer located along the LHC proton-proton collider at CERN and is ideally suited for the investigation of such phenomena. We present the latest results of 3-body charmless B decays where large local CP violating effects have been observed across various regions of the phase space [1,2]. These results are discussed in the light of recent theoretical developments that attempt to understand the origin of the large asymmetries [3] and their impact on future amplitude analyses.

Coherent State Operators in Cosmology and Gravity

Coherent States (CS) are widely used in physics, and quantum gravity is not an exception. However, the application of CS in the construction of operators is rather unexplored in the areas of quantum gravity and quantum cosmology. In my talk, I will present how CS can be used to define “coherent state operators” via a procedure known as “coherent state quantization” [1]. This procedure produces operators with inbuilt good semiclassical properties, while at the same time preserving typical quantum attributes (e.g., discreteness of spectra). Examples of such coherent state quantization will cover: (1) operators on homogeneous isotropic quantum cosmology [2] (based on the affine group); (2) possible extensions to Bianchi I case; (3) simple operators on $L_2(SU(2), d\mu_H)$.

Symmetry, Physical Theories and Theory Changes

We discuss the problem of theory change in physics. We propose a characterization of the concept of a theory in physics based on symmetries. The proposed characterization is compatible with the modern ideas in philosophy of science, e.g. the semantic approach to a scientific theory. Our approach is conceptually simple. It also allows an analysis of the problem of the mathematical structure and hints at a logic of discovery. As a case-study we consider the theory of kinematics of particles in distinct space-time backgrounds. The problem of theory change can be framed in terms of the notions of Inonu-Wigner contraction/extension of groups of symmetry. The notions presented here are strongly based on the notorious Bargmann-Wigner program. The talk is based on joint work with Marc Lachieze-Rey and Samuel Simon [1].

From DGT to dRGT: a review of “massive gravity” theories

Motivated in part by the wish to “replace” dark energy by a large distance modification of gravity, a large body of works has lead to a better understanding of properties and pathologies of theories of “massive gravity”, and closely related models such as “galileons”. This body mainly developed from the Dvali-Gabadadze-Porrati (DGP) model which was proposed almost 15 years ago and was the first framework which linked explicitly the cosmic acceleration with a large distance modification of gravity - and culminated with the more recent de Rham-Gabadadze-Tolley (dRGT) theory which is now believed to avoid certain pathologies present in previous constructions. Inbetweeen, these works also lead to several other proposals, many of which using the “Vainshtein mechanism” to hide at intermediate distances effects which only show up at cosmological scales. I will review these works stressing in particular the left over open questions.
Leptogenesis and low energy neutrino data

I will review the status of thermal leptogenesis and how this, in combination with low energy neutrino data, can be used as a powerful tool to probe models of new Physics. I will discuss how the possibility to realise independence of the initial conditions (strong thermal leptogenesis) relies on a special right-handed neutrino mass pattern and require quite special conditions, in particular a deviation of light neutrino masses from the hierarchical limit that can be tested in future years with cosmological observations. Intriguingly the set of conditions for strong thermal leptogenesis can be realise within SO(10)-inspired leptogenesis and in this case one obtains a set of definite predictions on future low energy neutrino measurements. Interestingly this solution requires non vanishing reactor mixing angle, now robustly established in reactor neutrino experiments, and a negative neutrino oscillation CP violation invariant parameter, as hinted by recent neutrino oscillation experimental results.

A new multiwavelength lepto-hadronic model of astrophysical jet emission

In the last few years, the rapid development of gamma-ray observations has open a new window on X-ray binaries (XRBs) sources, with at least one solid detection so far. Associated with these gamma-ray are neutrino emission. In this talk we introduce a new lepto-hadronic model that is based on successful work fitting the lower energy, broadband spectra of XRBs in the compact jet-dominated state. Protons (and electrons) are accelerated throughout the jet and cool via radiation and inelastic collisions, and we calculate spectral energy distributions (SEDs) including both hadronic and leptonic induced processes. We present new predictions for the gamma-ray fluxes in the GeV–TeV range. This model can also be scaled to describe the SEDs of low-luminosity active galactic nuclei such as our own Galactic Center black hole Sgr A*.

Energy-Momentum Tensor in Electromagnetic Theory and Gravitation from Relativistic Quantum Equations

Recently, several discussions on the possible observability of 4-vector fields have been published in literature. Furthermore, several authors recently claimed existence of the helicity=0 fundamental field. We re-examine the theory of antisymmetric tensor fields and 4-vector potentials. We study the massless limits too. In fact, a theoretical motivation for this venture is the old papers of Ogievetskiĭ and Polubarinov, Hayashi, and Kalb and Ramond. Ogievetskiĭ and Polubarinov proposed the concept of the notoph, whose helicity properties are complementary to those of the photon. We analyze the quantum field theory with taking into account mass dimensions of the notoph and the photon. It appears to be possible to describe both photon and notoph degrees of freedom on the basis of the modified Bargmann-Wigner formalism for the symmetric second-rank spinor. Next, we proceed to derive equations for the symmetric tensor of the second rank on the basis of the Bargmann-Wigner formalism in a straightforward way. The symmetric multispinor of the fourth rank is used. Due to serious problems with the interpretation of the results obtained using the standard procedure we generalize it and obtain the spin-2 relativistic equations, which are consistent with the general relativity. Thus, in fact we deduced the gravitational field equations from relativistic quantum mechanics. The relations of this theory with the scalar-tensor theories of gravitation and f(R) are discussed. Particular attention has been paid to the correct definitions of the energy-momentum tensor and other Noether currents in the electromagnetic theory, the relativistic theory of gravitation, the general relativity, and their generalizations. We estimate possible interactions, fermion-notoph, graviton-notoph, photon-notoph, and conclude that they will be probably seen in experiments in the next few years.
Gravitational waves attenuation in a non-perturbative spinorial vacuum

The propagation of gravitational waves on the background of non-perturbative vacuum filled with a spinor field is considered. It is shown that there are several distinctions with the propagation of gravitational waves in a flat space: (a) there exists a phase shift between $h_{yy}$ and $h_{zz}$ waves; (b) there exists an attenuation of waves; (c) for given frequency there exist two waves with different wave vectors. The experimental verification of obtained results is discussed. It is shown that the experimental measurements of such waves give us the tools for the investigation of non-perturbative quantum field theories.

Eckstein Michal (UJ)

Causal structure for noncommutative geometry

Noncommutative Geometry à la Connes offers promising frameworks for models of fundamental interactions. To guarantee the correct signature, the theory of Lorentzian spectral triples has been developed. I will briefly summarise its main elements and show that it can accommodate a sensible notion of causality understood as a partial order relation on the space of states on an algebra. For almost-commutative algebras of the form $C^\infty(M) \otimes A_f$, with $A_f$ being finite-dimensional, the space of (pure) states is a simple product of space-time $M$ and an internal space. The exploration of causal structures in this context leads to a surprising conclusion: The motion in both space-time and internal space is restricted by a “finite speed of light” constraint. I will explain the latter on 2 simple toy-models.

Friedmann equation and the emergence of cosmic space

This talk is based on [1]. We show that Padmanabhan’s conjecture for the emergence of cosmic space [2] holds for the flat Friedmann-Robertson-Walker universe in Einstein gravity but does not hold for the non-flat case unless one uses the aerial volume instead of the proper volume. We also show that various works extending Padmanabhan’s conjecture to non-Einstein and non-flat cases have serious shortfalls. This analysis is done using the Friedmann equation with the further assumptions of the holographic principle and the equipartition rule of energy.

Dark Matter in the Milky Way

We review most dynamical constraints on the shape of the gravitational field in the Milky Way, and on its corresponding dark matter halo. We review observational constraints in the central parts (core or cusped distribution), in the solar neighbourhood (local dark matter density) and in the outer parts (virial mass), and also point out various caveats, systematic effects and common misconceptions.

Feix Martin (Technion)

Tracing the cosmic velocity field at $z \sim 0.1$ from galaxy luminosities in the SDSS DR7

Spatial modulations in the distribution of observed luminosities (computed using redshifts) of around $5 \times 10^5$ galaxies from the SDSS Data Release 7, probe the cosmic peculiar velocity field out to $z \sim 0.1$ [1]. Allowing for luminosity evolution, the $r$-band luminosity function, determined via a spline-based estimator, is well represented by a Schechter form with $M^* (z) = \log_10 h = -20.52 - 1.6(z - 0.1) \pm 0.05$ and $\alpha = -1.1 \pm 0.03$. Bulk flows and higher-velocity moments in two redshift bins, $0.02 < z < 0.07$ and $0.07 < z < 0.22$, agree with the predictions of the $\Lambda$CDM model, as obtained from mock galaxy catalogs designed to match the observations. Assuming a $\Lambda$CDM model, we estimate $\sigma_8 \approx 1.1 \pm 0.4$ for the amplitude of the linear matter power spectrum, where the low accuracy is due to the limited number of galaxies. While the low-$z$ bin is robust against coherent photometric uncertainties, the bias of results from the second bin is consistent with the $\sim 1\%$ magnitude tilt reported by the SDSS collaboration. The systematics are expected to have a significantly lower impact in future datasets with larger sky coverage and better photometric calibration.

References:
Constraints on chiral gravity through the CMB polarization

If parity invariance is broken in the primordial universe, the cosmic microwave background $TB$ and $EB$ cross-correlations, usually vanishing, become non zero. Their detection would then constrain the level of parity violation, $\delta$. I propose to present forecasts on the detection of this parameter by realistically estimating the uncertainties on the $TB$ and $EB$ spectra via the pure pseudo spectrum method, which efficiency has been shown in [1]. I will present the results of this forecast [2] in the case of two typical experimental setups: a small-scale experiment and a large scale survey. Our results show that no constraints can be put on $\delta$ in the former case. However a range of model would be accessible with a future CMB satellite-like mission: for instance, a parity violation of at least 50% with $r = 0.2$ could be detected.

References

Fiziev Plamen (JINR) Dark Energy and Dark Matter in Stars Physic

This talk is based on papers [1,2,3]. We present the basic equations and relations for the relativistic static spherically symmetric stars (SSSS) in the model of minimal dilatonic gravity (MDG) which is locally equivalent to the $f(R)$ theories of gravity and gives an alternative description of the effects of dark matter and dark energy. The results for the simplest form of the relativistic equation of state (EOS) of neutron matter are represented. Our approach overcomes the well-known difficulties of the physics of SSSS in the $f(R)$ theories of gravity introducing two novel EOS for cosmological energy-pressure densities and dilaton energy-pressure densities, proper boundary conditions, as well as justifying the domain of SSSS in the phase space of the generalized Tolman-Openheimer-Volkov equations. It is shown that dark energy and dark matter play an essential role in the structure of SSSS due to natural chameleon like effect of MDG.

Some remarks on new numerical estimations of the Rees-Sciama effect

In previous editions of Frontiers of Fundamental Physics Symposia, [1,2,3,4,5] we have presented our numerical computations of Cosmic Microwave Background (CMB) anisotropies at high ℓ’s. We have adapted our algorithm to calculate such anisotropies through different N-body codes: Particle-Mesh (PM), linear and parallel Adaptive-Particle-Particle-Particle-Mesh (AP3M) Hydra codes. This way we have been able to compute weak lensing, Rees-Sciama (RS) and Sunyaev-Zel’dovich contributions to the CMB anisotropy. The use of parallel AP3M makes more accurate computations [6,7]. In 2006, we computed RS effect using a PM N-body code [8]. In this work, we present the improvements on the computation of RS contribution using parallel Hydra code. We also make some remarks on the coupling of contributions at high ℓ’s.

References

Charge Quantization from a Number Operator

In the early seventies, Günaydin and Gürsey discovered $SU_c(3)$ quark structure in the split octonions, [1]. Using their anti-commuting ladder operators, $\alpha_i$, we show a direct route to a new $U(1)$ generator. This $U(1)$ generator behaves like electric charge, thereby allowing us to further identify states behaving like the electron and neutrino.

Our proposed electric charge turns out to be proportional to a number operator, consequently illuminating why it is quantized.

Using only this trio of ladder operators, and their conjugates, we construct a pair of minimal left ideals, which is shown to transform under $SU_c(3)$ and $U_m(1)$ as does a full generation of the standard model.

Distorting General Relativity: Gravity’s Rainbow and $f(R)$ theories at work

The talk is based on the results of Ref. [1], where we compute the Zero Point Energy in a spherically symmetric background combining the high energy distortion of Gravity’s Rainbow [2] with the modification induced by a $f(R)$ theory. Here $f(R)$ is a generic analytic function of the Ricci curvature scalar $R$ in 4D and in 3D. The explicit calculation is performed for a Schwarzschild metric [3]. Due to the spherically symmetric property of the Schwarzschild metric we can compare the effects of the modification induced by a $f(R)$ theory in 4D and in 3D. We find that the final effect of the combined theory is to have finite quantities that shift the Zero Point Energy. In this context we setup a Sturm- Liouville problem with the cosmological constant considered as the associated eigenvalue. The eigenvalue equation is a reformulation of the Wheeler-DeWitt equation which is analyzed by means of a variational approach based on gaussian trial functionals. With the help of a canonical associated eigenvalue. The eigenvalue equation is a reformulation of the Wheeler-DeWitt equation which is

LSS with angular cross-correlations: Combining Spectroscopic and Photometric Surveys

The search for the nature of the dark sector relies on the combination of multiple techniques and probes, from both spectroscopic and photometric data. This matches well with the fact that some probes are intrinsically 3D (like RSD) and some 2D (like WL). But to get the best constraints we need to combine all of these. We show how using angular cross-correlations we can recover the full 3D galaxy clustering information, including BAO and RSD in spectroscopic surveys. This allows the combination of spectroscopic and photometric galaxy surveys, including photo-z error calibration and addition of WL. We show some application of these ideas in current data and simulations and show how overlapping surveys result in both better constrains and better understanding of systematic errors.

Schema or not schema? that could be the question of teacher

This research focuses on written language and systems of signs to study the learning of scientific concepts [1]. It proposes to show that students (Grade 10 [aged 15]) mobilize ideas about gas in different ways in regard to the semiotic registers (text or diagram) proposed during an assessment. Our study adopts a socio-constructivist approach of learning and develops a theoretical framework, articulating elements from the didactic of physics with semiotics concepts of Duval [2]. It propose to show that students (Grade 10 [aged 15]) mobilize ideas about gas in different ways in regard to the semiotic registers (text or diagram) proposed during an assessment. Our study adopts a socio-constructivist approach of learning and develops a theoretical framework, articulating elements from the didactic of physics with semiotics concepts of Duval [2]. We give a test with questions (using simultaneously text and diagram) to approximately 90 students just after a teaching sequence on gas. We categorize with the software Sphinx students’ answers and diagram. This analysis has excellent intra-analist reliability of our coding with the best level of reproducibility (Cohen’s Kappa test) and all our results are statistically significant (test of Khiz). Our results show that: (I) situations affect the mobilization of students’ ideas in regard to the semiotics registers involved in the assessment, (II) the semiotics registers have an effect on the mobilization of students’ ideas according to the facets of knowledge. Students are much more efficient in the register of: (a) schema to use facets about particles contained in gas and it homogeneous distribution and (b) text to mobilize their ideas about the action of gas, (III) the semiotic registers used in the tasks of the teaching sequence on gas could possibly be related to the mobilization of students’ ideas in the semiotics registers involved during the assessment. The implications of this work in teaching and research in didactic of physic are important. It allows to have a better consideration of the semiotic register to assess students’ knowledge.

High Energy Phenomena at the Center of our Galaxy

I will review the recent results on the high-energy phenomena occurring in the region of the Galactic Center by first describing the structure and the components of this fascinating area of the sky and then reporting the main discoveries that have been obtained in X-rays and gamma-rays. Several of these results indicate that the Galactic Center was the site of a powerful activity in the past, possibly driven by the central supermassive black hole, Sgr A*, that, today, appears very dim and quiet in contrast with the exuberant activity displayed by other galactic nuclei. I will try to put these results in context with the general picture we have from the observations of the nuclei of external galaxies to see if this can lead to some new insights on the impact of the galactic supermassive black hole on its close environment and on the whole Galaxy.

A brief overview of loop quantum cosmology and its potential observational signatures

Loop quantum cosmology (a symmetry-reduced quantum model of the Universe inspired by loop quantum gravity) extends the inflationary paradigm to the Planck era: the big bang singularity is replaced by a quantum bounce naturally followed by inflation. Testing for these models requires to compute the amount of cosmological perturbations produced in this quantum background and subsequently derives their footprints on the cosmic microwave background. I propose to review two theoretical approaches treating for cosmological perturbations in a quantum background [1,2], making their respective assumptions and methodology as explicit as possible. I will then show the observational consequences of those treatments focusing on the specific case of the cosmic microwave background anisotropies as a probe of the primordial Universe [3].

Cosmology with Galaxy Redshift Surveys

After more than fifteen years, the discovery that the Universe is accelerating emerges as one of the turning points in the history of cosmology, as witnessed by the 2011 Nobel Prize in Physics to Perlmutter, Riess and Schmidt. Yet, the origin of the accelerated expansion is a mystery. One possibility is that the Universe is permeated by a “dark energy” producing a kind of gravitational repulsion. Alternatively, perhaps the very equations of General Relativity need to be modified or generalized to higher-dimensional worlds.

Galaxy redshift surveys are one of the experimental pillars that contributed significantly to build this overall scenario and even larger projects are ongoing or planned, with the goal of understanding the nature of cosmic acceleration. In my talk I will review this situation and show how redshift surveys allow us to possibly break the degeneracy between dark energy and modified gravity by measuring both the expansion rate and the growth rate of structures. I will present recent examples, including results from the new VIPERS survey at the ESO Very Large Telescope. I will then discuss status and plans for the ultimate dark-energy experiment, the ESA satellite Euclid, which is due to launch in 2020. Euclid promises to reach percent accuracies on the measurement of cosmological parameters, with unprecedented control of systematic effects.
A fluid of diffusing particles and its cosmological behaviour

1. We discuss Einstein gravity for a fluid consisting of particles interacting with an environment of some other particles. The environment is described by a time-dependent cosmological term which is compensating the lack of the conservation law of the energy-momentum of the dissipative fluid. The dissipation is approximated by a relativistic diffusion in the phase space. We are interested in a homogeneous isotropic flat expanding Universe described by a scale factor $a$. At an early stage the particles are massless. We obtain explicit solutions of the diffusion equation for a fluid of massless particles at finite temperature. The solution is of the form of a modified Jüttner distribution with a time-dependent temperature. At later time Universe evolution is described as a diffusion at zero temperature with no equilibration. We find solutions of the diffusion equation at zero temperature which can be treated as a continuation to a later time of the finite temperature solutions describing an early stage of the Universe. The energy-momentum of the diffusing particles is defined by their phase space distribution. A conservation of the total energy-momentum determines the cosmological term up to a constant. The resulting energy-momentum inserted into Einstein equations gives a modified Friedmann equation. Solutions of the Friedmann equation depend on the initial value of the cosmological term. The large value of the cosmological constant implies an exponential expansion. If the initial conditions allow a power-like solution for a large time then it must be of the form $a \sim \tau$ (no deceleration, $\tau$ is the cosmic time). The final stage of the Universe evolution is described by a non-relativistic diffusion of a cold dust. The model is studied in [1]. The relativistic diffusion in [2-6].

II. As a second step we discuss extensions of the model I. We discuss interactions which lead to relativistic diffusion. In particular, we show that quantized electromagnetic fields and gravitons can lead to diffusion. Such a diffusion must be included on the rhs of Einstein equations if the quantized degrees of freedom are not treated explicitly as dynamical variables (some earlier work on the effect of gravitons is in [8,9]). Next, we consider the perturbation of the homogeneous metric of the model I in order to study the role of diffusion in the spreading of inhomogeneities at an early stage of the hot universe.

Curved polyhedra
We describe how to reconstruct a constant curvature tetrahedron given four holonomies whose product is the identity. We construct a phase space describing the shapes of curved tetrahedra. We give a conjecture for the generalization of Minkowski’s theorem to spaces of constant curvature. This establishes a new route to the description of four dimensional quantum gravity with a cosmological constant.

IceCube and the Discovery of High-Energy Cosmic Neutrinos
The IceCube project has transformed one cubic kilometer of natural Antarctic ice into a neutrino detector. The instrument detects 100,000 neutrinos per year in the GeV to PeV energy range. Among those, we have recently isolated a flux of high-energy cosmic neutrinos. I will discuss the instrument, the analysis of the data, and the significance of the discovery of cosmic neutrinos.

Haro Jaume (UPC) July, 16, 15h30 – 16h00, Amphitheatre "Massiani", Quantum Gravity
Matter Bounce Scenario in F(T) gravity
The CMB map provided by the Planck project constrains the value of the ratio of tensor-to-scalar perturbations, namely $r$, to be smaller than 0.11 (95 % CL). This bound rules out the simplest models of inflation. However, recent data from BICEP2 is in strong tension with this constrain, as it finds a value $r = 0.20_{-0.05}^{+0.07}$ with $r = 0$ disfavored at $7.0\sigma$, which allows these simplest inflationary models to survive. The remarkable fact is that, even though the BICEP2 experiment was conceived to search for evidence of inflation, its experimental data matches correctly theoretical results coming from the matter bounce scenario (the alternative model to the inflationary paradigm). More precisely, most bouncing cosmologies do not pass Planck’s constrains due to the smallness of the value of the tensor/scalar ratio $r \leq 0.11$, but with new BICEP2 data some of them fit well with experimental data. This is the case with the matter bounce scenario in $F(T)$ gravity.
Weak gravitational lensing

Weak gravitational lensing by inhomogeneities along the line-of-sight alters the shapes, sizes and fluxes of distant sources such as galaxies, and distorts the pattern of continuous fields such as the microwave background radiation. In this talk I will review this relatively young scientific field, with particular emphasis on its power for studying dark energy and modified gravity. I will discuss the challenges it faces, summarize results from recent survey analyses, and finally consider the prospects for the future.

Designing and evaluating new approaches to instruction

Results from research indicate that many students emerge from traditional undergraduate science courses without having developed a functional understanding of important basic concepts. These findings have motivated changes in undergraduate courses in the sciences, mathematics, and engineering. Many newer strategies are described as “interactive” in that students are expected to engage in discussions with each other, and with professors during class time. Many strategies also involve paying attention to the ideas and beliefs that students have upon entering the classroom, ideas and beliefs that have they developed during previous formal instruction, and through their everyday experience with the natural world. Evaluating the effectiveness of these strategies requires a careful assessment of the goals of instruction and attention to a number of variables, many of which cannot be controlled. Examples will be used to illustrate the process of designing and evaluating instructional approaches and materials. The context will be physics but analogies can be made to other disciplines.

A novel approach to characterising quantum theory based on limited information and complementarity

The last decade has seen a wave of reconstructions and characterizations of quantum theory using the formalism of generalized probability theory. In this talk, we shall outline a novel (operational) approach to characterizing and reconstructing quantum theory which gives primacy to limited information and complementarity rather than the probability structure. In particular, we consider an observer interrogating a system with binary questions and analyze the consequences of (1) a postulate asserting a limit on the (simultaneous) information the observer can acquire about the system, and (2) a postulate asserting the existence of complementarity on the set of possible questions. We explain how the ensuing compatibility and complementarity structure of the binary questions implies many features of qubit quantum theory in an elegant way (e.g. three-dimensionality of the Bloch sphere, the entanglement structure of two qubits, absence of third or higher order interference and many other features). Time permitting, we shall also sketch how this program can be completed to a full reconstruction of quantum theory by adding further ingredients.

Quantum formalism for systems with temporally varying discretization

A canonical quantum formalism for discrete systems subject to a discretization changing dynamics is outlined. This framework enables one to systematically study (non-)unitarity of such dynamics, the role of canonical constraints and the fate of Dirac observables on temporally varying discretizations. It will be illustrated how the formalism can also be employed to generate a vacuum for a scalar field on an evolving lattice. Implications for the dynamics in simplicial quantum gravity models are commented on.

Physical predictions from lattice QCD

Lattice QCD is a method for solving the nonperturbative dynamics of low energy QCD from first principles. Over the last few years, the field has matured considerably and reliable experimental predictions have been obtained in many areas. I will summarise the most important developments, give an overview of the currently attainable precision on key observables such as the hadron spectrum or the light quark masses and discuss some open challenges and future perspectives of the field.
Symmetries in Large Scale Structure

We will discuss the role of symmetries in three different areas of large scale structure:
1. how to test the equivalence principle using black holes in centers of galaxies;
2. how to measure gravitational redshifts using parity-violating signatures in correlation functions;
3. how spontaneously broken symmetries give us fully non-perturbative relations between \( N \) and \( N+1 \) point functions.

Iglesias-Zemmour Patrick (I2M, CNRS)

Symplectic Diffeology and Moment Maps

I shall discuss the general framework of symplectic diffeology through examples, in infinite dimension and in singular context: infinite projective space, orbifolds, symplectic irrational tori etc. I will discuss how the condition to be symplectic in diffeology involves at the same time the universal moment map, relative to the automorphisms of the structure, and the decomposition of the space into orbits under the automorphisms. I will also discuss a family of examples that mixes infinite dimension and singular quotients: the infinite quasi-projective spaces.

That will show how diffeology is an operable theory and handles the objects of mathematical physics in a simple but rigorous way.

Ilic Stéphane (IRAP)

The baryon fraction in clusters and scaling relations in LCDM from X-ray and Planck data

Clusters are known to be a powerful probe of cosmology; however, their use is also known to be limited by the degeneracy that exist between their mass and their temperature. Here, we show that using the CMB temperature fluctuations (as measured by Planck) in conjunction with the temperature distribution function of local clusters, allows to break this degeneracy for a specified model (such as the concordance LCDM). The consistency of the aforementioned model can then be tested on baryon fraction and Sunyeav-Zeldovich scaling laws.

Joshi Kiran (UoM)

Measurement of EW production of \( Z + 2j \) at the LHC

The electroweak production of a \( Z \)-boson in association with dijets (\( Z + 2j \)), which includes the vector boson fusion process, is an important background to the vector boson fusion production of a Higgs boson in association with dijets. Both ATLAS [1] and CMS [2,3] have made measurements of the electroweak production of \( Z + 2j \). In this talk the methods and results of extracting the electroweak component of the cross section are presented. Detector-corrected distributions of hadronic jets are also presented and show sensitivity to the electroweak production process. The distributions can be used to probe the different approaches to generating both QCD and electroweak \( Z + 2j \) events.

Precanonical quantization from the first principles to quantization of gravity

I review mathematical structures of the De Donder-Weyl (DW) Hamiltonian theory for fields, which does not require space-time decompositions. Those structures: the polysymplectic form, Poisson-Gerstenhaber brackets of differential forms, which represent dynamical variables, the bracket form of the DW Hamiltonian field equations, and the fundamental brackets, allow us to formulate a generalization of canonical quantization to the DW framework. Because the structures of DW Hamiltonian theory are intermediate between the Lagrangian and the canonical Hamiltonian level, and they don’t require splitting into the space and time and don’t consider the infinite dimensional spaces of field configurations, the corresponding approach is called precanonical quantization. I show how the quantization of fundamental brackets leads to a quantum theoretic formalism were the wave functions and operators are space-time Clifford algebra valued, and the role of the Schroedinger equation is played by a Dirac-like equation with the operator of the DW Hamiltonian function replacing the mass term. I briefly show how this approach allows to reproduce few simple results of quantum field theory and how the standard quantum field theory appears as a limiting case when the elementary volume parameter $1/k$, which appears in precanonical quantization, tends to zero (more details will be given in the talk at the session on mathematical physics). After this review, I will show how the approach of precanonical quantization works for quantization of gravity in the first order vielbein – spin-connection formalism. It will include a generalization of DW hamiltonian theory to the singular case, its quantization, formulation of the generalized Schroedinger equation for the wave function on the bundle of spin-connection coefficients over space-time, and the definition of the appropriate Hilbert space. In this framework the quantum space-time is discussed by the transition amplitudes between the values of spin-connection at different points of space-time, which can be determined from the equations of the theory. I will also discuss simple applications of the results in the context of quantum cosmology.

Off-shell Higgs signal and total width determination at the LHC

A substantial far-off-shell contribution to the Higgs boson signal in the $H \rightarrow ZZ$ decay mode [1] facilitates a novel, complementary approach to constraining the Higgs width $\Gamma_H$ at the Large Hadron Collider (LHC) [2]. A first experimental analysis [3] obtained $\Gamma_H < 22$ MeV (95% CL), which is 5.4 times the expected value in the Standard Model at the measured Higgs boson mass. I review the theoretical basis of the new approach and discuss its significance and potential in comparison to other methods to bound and measure the Higgs width at the LHC and future colliders.

Scalar field dark matter and pulsar timing observations

This talk is based on [1]. An ultralight free scalar field with mass around $10^{-21} - 10^{-22}$ eV is a viable dark mater candidate, which can help to resolve some of the issues of the cold dark matter on sub-galactic scales. We consider the gravitational field of the galactic halo composed out of such dark matter. The scalar field has oscillating in time pressure, which induces oscillations of gravitational potential with amplitude of the order of $10^{-15}$ and frequency in the nanohertz range. We find that for a range of dark matter masses, the scalar field dark matter signal is comparable to the expected stochastic gravitational wave signal and can be detected by the planned SKA pulsar timing array experiment.

Roots and prespective of Bergmann-Einstein scalar tensor theory: the unpublished paper

In 1938 long time before Dicks, Branes and Jordan work on scalar-tensor theory, Einstein and Bergmann introduce the modern viewpoint in which a four-dimensional theory that coincides with Einstein-Maxwell theory at long distances is derived from a five dimensional theory with complete symmetry among all five dimensions. But then they drew back, modifying the theory in a way that spoiled the five-dimensional symmetry and looks contrived to modern readers. The reason was that the more symmetric version of the theory predicts the existence of a new long range field (a massless scalar field), a prediction which Einstein and Bergmann refuse to admit.

We know today that, with their similar, but slightly different predictions for physical phenomena, scalar-tensor theories turned out to be the first significant challenge to Einstein’s theory in over forty years. But as it turned out, standard Einstein theory fared better in these tests than any of the alternatives. In consequence, in the 1970’s, interest in these alternative theories dropped dramatically. However, from the 1980’s on, new discoveries and theories have led to renewed interest in scalar-tensor gravity.

In this lecture I’ll back to Begmann-Einstein paper and explain the issue of their drew back and the epistemological statut of the scalar tensor kind theories with respect to the last observations.

Cosmological tests of gravity

The discovery of the accelerated expansion of the Universe has come relatively late in our study of the cosmos, but in showing that gravity can act repulsively, it has opened up many new questions about the nature of gravity and what the Universe might contain. Is the acceleration being driven by dark energy? Or is general relativity (GR) itself in error, requiring a modification at large scales to account for the late acceleration? Structure formation in our Universe can be different even if the geometry of the homogeneous and isotropic universe is the same in these two classes of models, offering a possibility to distinguish between them observationally. Non-linear structure formation is complicated by the fifth force that commonly appears in modified gravity models and new techniques are required to analyse it. We will discuss novel methods to test GR on cosmological scales, building on the recent developments of N-body simulations for modified gravity.

**July, 17, 14h30 – 15h00, Room 405, Frontiers of Fundamental Physics**

Dynamics of histories

We propose an unified framework, based on the notion of histories, which applies to time dynamics and to field theories. It accepts a Lagrangian and a Hamiltonian formulations, both entirely covariant in the case of field theories. Dynamical equations and conservation laws take a very simple universal expression. Developing differential calculus in the (infinite dimensional) space of histories, we define a generalized symplectic form. It leads very naturally to the multisymplectic formalism in field theories (the usual symplectic form for time dynamics appearing as a particular case) and it provides the usual on-shell symplectic form (in the space of solutions). We apply to first order canonical general relativity.

Fitting the Fermi-LAT GeV excess: on the importance of the propagation of electrons from dark matter

An excess of gamma rays at GeV energies has been detected in the Fermi-LAT data. This signal comes from a narrow region around the Galactic Center and has been interpreted as possible evidence for light (30 GeV) dark matter particles. Focussing on the prompt gamma-ray emission, previous work found that the best fit to the data corresponds to annihilations proceeding into b quarks, with a dark matter profile $r^{-1.2}$. In this talk, I will show that this is not the only possible annihilation set-up. More specifically, I will show how including the contributions to the gamma-ray spectrum from inverse Compton scattering and bremsstrahlung from electrons produced in dark matter annihilations, and undergoing diffusion through the Galactic magnetic field, drastically modifies the spectrum, in particular for leptonic final states.
Hyperbolic PDEs with non-commutative time

In this talk, I will report on joint work with Rainer Verch [1] on hyperbolic PDEs with non-commutative time, i.e. linear integro-differential equations of the form \((D + \lambda W)f = 0\), where \(D\) is a (pre-)normal hyperbolic differential operator on \(\mathbb{R}^n\), \(\lambda \in \mathbb{C}\) is a coupling constant, and \(W\) a regular integral operator which is non-local in time, so that a Hamiltonian formulation is not possible. Such equations appear in the context of wave or Dirac equations on non-commutative deformations of Minkowski space. It will be discussed that at small coupling, the hyperbolic character of \(D\) is essentially preserved, unique advanced/retarded fundamental solutions can be constructed, and the acausal behavior of the solutions is well-controlled. Although the Cauchy problem is ill-posed in general, a scattering operator can be calculated which describes the effect of \(W\) on the space of solutions of \(D\).

It is also described how these results can be used for the analysis of classical and quantum field theories on non-commutative spaces.

Background independence of GR and in LQG

The physical meaning of the diffeomorphisms in the general relativistic theories will be discussed, the issues of time evolution in terms of the Dirac observables and physical Hamiltonian will be addressed. New proposals for geometric deparametrization will be presented. The quantum part of the lecture will concern the canonical LQG. New, improved formulations of the quantum Hamiltonian will be proposed. New applications for LQG will be offered. Original results that will be presented in this lecture were obtained in collaboration with: Dapor, Duch, Kaminski, Swiezewski, Alesci, Assanioussi, Dziendzikowski and Sahlmann.

Lewandowski Jerzy (UW) July, 18, 15h00 – 15h30, Room 404, Quantum Gravity

Exact formulation of the quantum scalar constraint in LQG

Several new applications for LQG will be presented. The first one is a new quantum representation of the gravitational scalar constraint. In this representation, for the first time in the literature, the quantum C(N) itself preserves the Hilbert space for every laps function N. Owing to that property, solutions to the quantum constraints of vacuum GR can be well defined by the spectral decomposition and set a physical Hilbert space. Our representation admits also a new proposal of the quantum physical Hamiltonian of the Novelli-Smolin model of gravity coupled to the mass-less Klein-Gordon time field. The third application we propose, is a new operator for the quantum Hamiltonian of the Klein-Gordon Scalar field coupled to LQG. Our new framework captures the degrees of freedom of the scalar field lost in the framework in which time is deparametrized by the scalar field.

Linsefors Linda (LPSC) July, 16, 16h00 – 16h30, Amphi "Massiani", Quantum Gravity

LQC on curved FLRW space time

This talk is based on [1,2]. Loop quantum cosmology predicts a bounce instead of the big bang. Anisotropies grow in a contracting universe an should therefore not be neglected at the bounce. In this talk I will discuss how the bounce and the following inflation is affected by anisotropies in effective Bianchi-I loop quantum cosmology.

Lizzi Fedele (UNINA)
Noncommutative Geometry, the Spectral Action and Fundamental Symmetries

Noncommutative Geometry, i.e., the spectral data of generalized spaces, provides a fruitful approach to the standard model of fundamental interactions. This is done via the spectral action, which is a function of the Dirac operator. It is a regularized trace, cutoff at a scale. This cutoff is sty point in which all gauge interactions are equally strong, and it may represent a phase transition of the theory to a pre geometric phase. I will discuss the role of this field theory cutoff, and the symmetries and structure of space-time that one can infer from the spectral action.

Luminet Jean-Pierre (LUTH)
Lemaître’s Big Bang

We provide an epistemological analysis of the developments of relativistic cosmology from 1917 to 1965, based on the seminal articles by Einstein, de Sitter, Friedmann, and a special focus on Georges Lemaître, the true father of Big Bang theory. In particular we solve the controversy about the so-called Hubble’s law, that was first presented in a Lemaître’s article of 1927 published in French, but disappeared in its English translation of 1931. It appears that most of the ingredients of the present-day standard cosmological model, such as the acceleration of the expansion due to a repulsive dark energy, the interpretation of the cosmological constant as vacuum energy or the possible non-trivial topology of space, had been anticipated by Lemaître, although his papers remain desperately unquoted.

López-Corredoira Martin (IAC)
The Twilight of the Scientific Age

There are some symptoms which indicate a decline of our scientific culture. First, our society is drowned in huge amounts of knowledge. Most of it is about research of little importance to progress our world view or produces no advances in the basic fundamentals of pure science. Instead, we invent countless technical applications or investigate secondary details. Second, in the few fields where some important aspects of unsolved questions have arisen, powerful groups of administrators of science control the flow of information. They have inherent biases resulting in a preference for consensus truths, rather than having objective discussions within a scientific methodology. This process gives few guarantees that we are obtaining solid new truths about nature. Finally, should the current scientific process continue the way it is, individual creativity is condemned to disappear. Indeed, truly creative scientists are substituted by large corporations of administrators and politicians of science specialised in searching ways of getting money from States in megaprojects with increasing costs and diminishing returns.
Tests on the Expansion of the Universe

Almost all of the cosmologists accept nowadays that the redshift of the galaxies is due to the expansion of the Universe (cosmological redshift), plus some Doppler effect of the peculiar motions, but can we be sure of this fact by means of some of another independent cosmological test? In this talk, I will review some of the recent applications of this search: angular size test [1], Tolman or surface brightness test [2], in which we need to assume a very strong evolution of the galaxy sizes to fit the data with the standard cosmology; or Alcock-Paczynski test [3], an evaluation of the ratio of observed angular size to radial/redshift size, which is independent of the evolution of galaxies but it is affected by the redshift distortions produced by the peculiar velocities of the gravitational infall. In this last test, it results that the standard cosmology is compatible with the data but also with some models of static Universe.

Magni Stefano (LUPM)
Revisiting the escape speed impact on dark matter direct detection

The knowledge of the high velocity tail of the WIMP velocity distribution has strong impact on the way direct detection (DD) may constrain or discover light WIMPs in the GeV mass range. Recently, there has been important observational efforts to measure the so-called Galactic escape speed at the position of the Earth, like for instance the analysis released in late 2013 by the RAVE Collaboration. We revisit the estimate of the astrophysical uncertainties on DD limits and sensitivity from this perspective. We show that a treatment that consistently correlates all relevant parameters (local circular velocity, dark matter density, distance to the Galactic center, escape speed) leads to significantly reduced systematic errors in DD sensitivity. We go beyond the Maxwellian velocity approximation generally used to compute the DD limits by means of ergodic distribution functions, where the previously mentioned correlations are automatic and result from a minimal set of input parameters. Finally, we test our semi-analytical model against cosmological simulations and discuss its relevance. We show that it provides a consistent and simple way to derive meaningful astrophysical uncertainties.
Marozzi Giovanni (DPT - Unige)  July, 16, 15h50 – 16h10, Amphi "Charve", Cosmology

The value of $H_0$ in the inhomogeneous Universe

In this talk I will show how local measurements of the Hubble expansion rate are affected by structures like galaxy clusters or voids. In particular, I will present a fully relativistic treatment of this effect, studying how clustering modifies the mean distance (modulus)-redshift relation and its dispersion in a standard ΛCDM universe. Our findings is that cosmic variance (i.e. the effects of the local structure) is, for supernova observations at small redshifts ($0.01 < z < 0.1$) of the same order of magnitude as the current observational errors. The cosmic variance has to be added to this observational uncertainties and it reduces the tension with the CMB measurement of $H_0$.

Geometry with a cut-off

Various aspects of fundamental physics – like renormalization in quantum field theory or some considerations about quantum gravity – point towards the existence of a cut-off in either the momentum or the position space. As a consequence, usual geometrical notions such as points and geodesic distance loose their meaningful. We will show how noncommutative geometry provide interesting tools to study the geometry of such “cut-off spaces”, including topological and metric aspects.

Martin Jérôme (IAP)  July, 17, 12h00 – 12h30, Amphi "Charve", Plenary Session 1

Inflation after Planck & BICEP2

The inflationary scenario is currently considered to be the most promising paradigm to describe the origin of the perturbations in the early universe. It corresponds to a period of accelerated expansion before the hot Big Bang phase. Inflation is typically achieved using scalar fields, and it is the quantum fluctuations associated with the scalar fields that are responsible for the creation of the primordial perturbations. The perturbations generated during inflation leave their signatures as anisotropies in the Cosmic Microwave Background (CMB). With the CMB anisotropies being measured to greater and greater precision, we are presently in an unprecedented situation of being able to arrive at strong constraints on the physics of the early universe. In this talk, after a brief introduction to inflation, I describe the implications of the recently released Planck & BICEP2 data for inflation and discuss what are the “best” inflationary scenarios.

Primordial non-Gaussianity, present status and future prospects

I will review both the general problem of the search for non-Gaussian signatures in cosmological perturbations, originated from inflation in the early Universe. I will discuss this issue both from the theoretical point of view and in connection with constraints coming from recent observations and future prospects for observing/constraining them.

Mathieu Aurore (CPPM)  July, 18, 17h00 – 17h20, Amphi "Charve", Astroparticle Physics

Multi-Messenger analysis with the ANTARES High Energy Neutrino Telescope

ANTARES is currently the largest operating neutrino telescope in the Northern Hemisphere, mainly sensitive to TeV neutrinos. Its main goal is the detection of high energy neutrinos from astrophysical sources, which would provide important insights about the processes powering their engines and would help understand the origin of high energy cosmic rays.

To identify unambiguously such sources, ANTARES has developed several online and offline programs to reveal possible time and/or space correlations of neutrino candidates with other cosmic messengers: photons (mainly X-rays and GeV/TeV gamma-rays through the search from Gamma-ray bursts or GeV-flaring blazars, but also in the optical domain through alert and follow-up programs), cosmic rays and gravitational wave bursts detected by the Virgo/LIGO interferometers. Some of the most relevant results of these multi-messenger analyses will be presented in this contribution.
Fuzzy Topology, Quantization and Gauge Fields

It was argued earlier that Dodson-Zeeman fuzzy topology (FT) represents the possible mathematical basis for quantum space-time structure. Here the quantization formalism related to it will be described.

As the example, the quantization of massive particles is considered, it’s shown that the coordinate uncertainty is generic in FT. FT fundamental set is maximal totally ordered subset. FT ordering relation is mainly concentrated over interval. In this framework it corresponds to the formal definition of fuzzy point and fuzzy weight.

In such approach massive particle $m$ can be described as the evolving fuzzy point $a_i(t)$ of $U$. It’s shown that the corresponding normalized $m$ density $w(x, t)$ evolves according to the flow continuity equation:

$$\frac{\partial w}{\partial t} = -\frac{\partial (vw)}{\partial x},$$

where $v(x, t)$ is $w$ flow local velocity. The independent $m$ parameters $w(x), \psi(x)$, which characterize $m$ state, can be unambiguously mapped to normalized complex function $\psi(x)$. Assuming space-time shift invariance, it’s proved that $\psi(x, t)$ evolution obeys to Schrödinger equation for arbitrary $m$ mass $\mu$, such theory can be also extended for 3-dimensional case. It’s proved also that in relativistic case $m$ evolution described by Dirac equation for spin $\frac{1}{2}$. Particle’s interactions on such fuzzy manifold are shown to be gauge invariant, the interactions of fermion multiplets are performed by Yang-Mills fields.

Mescia Federico (UB)  
Review of Flavour Physics

I will present a summary of what we learned so far from low-energy flavor observables, concerning on physics beyond the Standard Model (SM). In the past few years there has been a great experimental progress in quark and lepton flavour physics. In the quark sector, the validity of the SM has been strongly reinforced by a series of challenging tests. As I try to show, looking for physics beyond the SM via the Flavour Window is still a powerful tool thanks also to forthcoming results from LHC and future $B$ Factories.
Teaching modern physics in secondary school

The physics of the last century is now included in all EU curricula and in the last 10 years appear in all secondary textbooks, even if in not organic way. Although there are very different position as concern its introduction: conceptual knots in classical physics are quoted to argue the exclusion of modern physics in secondary school. Discussions are on goals, rationale, contents, instruments and methods, target students. The different proposals are relative to different goals: the culture of citizens, popularization, guidance, education. As concern what is considered useful to treat are considered: fundament, technologies and applications. Methods are: story telling of the main results, argumentation of crucial problems, integrated or as a complementary part in the curriculum. Modern physics in secondary school is a challenge which involves the possibility to transfer to the future generations a culture in which physics is an integrated part, not a marginal one involves curriculum innovation, teacher education and physics education research in a way that allows the students to manage them in moments of organized analysis, in everyday life, in social decisions. This innovation of curriculum outlines the request for new formative modalities, requires a school in which modern physics is presented as a cultural object that the teacher offers to the students not so much for them to be reproduced, but most of all, for them to be used in a creative way to face the interpretative problems as a competence in many contexts. For this scope it is necessary to undertake a revision of the contents and methods in school activities. Disciplinary knowledge should NOT be seen as static and definite, but in a progressive and continuous evolution, without split the product from its process, with a tight correlation between the many dimensions of knowledge. Disciplines have to become “maps”: conceptual ones for understanding and organizational ones for a guidance in the interpretation of experience. In this perspective modern physics is an integrated content in curricula. Our research focus is the building of formal thinking on 3 directions: 1) Learning processes and role of reasoning in operative hands-on and minds-on to interpret phenomena; 2) object - models as tools to bridge common sense to physics ideas and ICT contribution focusing on real time labs and modelling; 3) building theoretical way of thinking: a path inspired of Dirac approach to quantum mechanics. From our research in physics education some different proposals for the modern physics are: 1) The physics in modern research analysis technics: Resistivity and Hall Effect, Rutherford Backscattering Spectroscopy, Time Resolved Resistivity; 2) Explorative approach to superconductivity (a coherent paths), 3) Discussion of some crucial / transversal concepts both in classical physics and modern physics: state, measure, cross section, 4) Foundation of theoretical thinking: quantum mechanics.

Higher Symmetries of Laplace and Dirac operators - towards supersymmetries

In this talk, I will survey some of the results obtained in [3, 4, 5]. On a flat (pseudo-)Riemannian manifold, the higher symmetries of the Laplacian form an associative algebra of differential operators, determined by Eastwood in [1]. It plays a central role in higher spin field theory and give a geometric realization of a highly non-trivial object from Lie theory: the Joseph ideal [2]. Using quantization methods, I propose a simple proof of Eastwood’s result and extend it to the system Laplace + Dirac operators. In dimension 4, its higher symmetries are generated by the conformal supersymmetries discovered by Wess and Zumino [6].

Less teaching yields better learning

What is the state of teaching in higher education? Can we provide evidence of the efficacy of our teaching practices? Are we really satisfied with the results we achieve? Do we actually contribute to develop creativity, initiative, autonomy, risk assessment and taking, collaboration, and do we actually prepare our student to solve complex, often multidisciplinary problems in innovative ways? Can we do better with our limited resources? Is our investment in teaching sufficiently acknowledged and valued? Are the QS rankings more or less relevant than the Shanghai ones, those of the Times, or those of Leiden?

We frequently hear such questions uttered by disillusioned and demotivated academics. We are, all of us, well aware of the expectations and needs of society, but we often feel that we cannot respond satisfactorily. It is tempting to blame our students (“who aren’t any more like they used to be”), the shortcomings of secondary education, the pressures of competitive research, or even simply “the system”, i.e. the others. Shouldn’t we ask ourselves what we, as academics, could (or should) do to remedy the sorry state of affairs we so often deplore?

Solutions do exist! But we need to question our habits, our opinions, our intuitions, our traditions, our certainties. Also, if we are to change our teaching practices, we must do so based not on fads or on personal biases, but on validated results of well-run scientific experiments.

The talk will provide the author’s answers to the following questions:
— What is efficacy in higher education?
— Is higher education efficacious?
— Why should we try to achieve better efficacy in higher education?
— How can we achieve better efficacy in higher education?
— Which conditions should be met in order to achieve better efficacy in higher education?

High energy sources during the re-ionization epoch of the universe

The cosmic dark ages are one of the major frontiers in cosmology. So far, most models of the re-ionization have considered the ultraviolet radiation from massive stars formed in the first galaxies. I will show that high energy sources of X-rays and relativistic jets determined the early thermal history of the universe and maintained it ionized over large volumes of space until the first billion years of the universe, when feedback from super-massive black holes (AGN) took over. High energy sources from compact stellar objects had a direct impact on the properties of the faintest galaxies at high redshifts, the smallest dwarf galaxies in the local universe, and on the cold dark matter model of the universe.

Constraints on Higgs physics from EW precision measurements

The electroweak precision measurements offer a very powerful handle on the underlying mechanism of electroweak symmetry breaking and on the nature of the Higgs boson. In this talk, I will present current constraints on new physics beyond the Standard Model from the electroweak precision fit, and discuss the interplay between the electroweak precision fit and the Higgs measurements at the Tevatron and LHC.

Mollitor Pol (LAM)  
Cosmological N-body-hydro simulations of spiral galaxies and dark matter detection

We study three high resolution cosmological hydrodynamical simulations of Milky Way-sized halos including a comparison with the corresponding DM-only runs performed with the adaptive mesh refinement code RAMSES. We analyse the stellar and gas distribution and find one of our simulated galaxies with interesting Milky Way like features with regard to several observational tests. Thanks to consistently tuned star formation rate and supernovae feedback, we manage to obtain an extended disk and a flat rotation curve with the circular velocity and the dark matter density in the solar neighbourhood in agreement with observations. With a careful look at the derivation of the stellar-to-halo mass ratio, we also obtain competitive values for this criterion. Concerning the dark matter distribution, we explicitly show the interaction with the baryons and show how the dark matter is first contracted by star formation and then cored by feedback processes. In this consistent framework, we also study dark matter detection phenomenology which will be the subject of subsequent papers.

Learning physics : from the nature and origins of difficulties to an evolution of teaching

There is a general agreement that undergraduate physics education presents a global challenge leading to many pedagogical innovations designed to enhance student’s understanding of physical concepts. In France, current orientations focus on the development of inquiry based approaches with a model inherited from reforms in primary and secondary science education. Such an approach is promoted for its interactive nature placing students in a research-based environment. It is based on the view that designing the learning process should take into account the knowledge previously acquired by students ensuring that students fully understand the concepts involved and can apply their understanding to new situations. The purpose of that communication is to present long established results in physics education research and stress their impact on teaching practices. Using examples of scientific concepts known for presenting an obstacle to understanding, the communication aims at demonstrating that recurring ideas can be found amongst undergraduate students. These ideas might present a limited validity according to the scientific concepts. They are persistent and can be found amongst younger pupils, graduates, or teachers. They usually present a logic in a historical and cultural context. Many research studies indicate that the information presented through traditional science instruction is often incompatible with student’s knowledge and beliefs and consequently, students persist on holding their alternative ideas of physics concepts. This lead to advocate a deeper understanding of the process of learning and teaching physics and conditions to its efficiency through close collaborations between physics academics and physics education research academics.

Nadal Jordi (II. Physikalisches Institut)

Top production at the LHC

Latest LHC results of the top quark production are presented. With the focus on the ATLAS and CMS experiment I will present top quark production cross-section in the different channels and also the latest results on the single top production, giving the state-of-art measurements. I also include differential cross-section as well as top quark pair production in association with W/Z bosons.

Neu Christopher (UVa)

Search for tth in Run 1 at the LHC

With the discovery in 2012 of a Higgs boson at the LHC, the focus of the Higgs physics campaigns at the ATLAS and CMS experiments has transitioned from the search for the Higgs to the pursuit of the complete characterization of this new particle. This is an essential step that is necessary in the determination of whether this is the Higgs boson of the standard model, or a component of some other, more exotic explanation of the fundamental world. Principal among these characterizations is the understanding of the interaction strength, or coupling, between this Higgs boson and the other known fundamental particles; among these couplings, the largest and arguably the most important is that between the Higgs and the top quark, the most massive of the known fundamental particles. The only direct probe of this coupling is through the observation of Higgs boson production in association with top quarks at the LHC. In this talk, the search strategy and current status will be described, focusing on the results from the 2010-2012 Run 1 of the LHC, with also an eye toward future studies in Run 2. The observation of this process is one of the highest-priority aspects of the current LHC physics program.
Nusser Adi (IIT)

Dynamics of the Cosmic Web

A critical assessment of the observed large scale structure will be presented, starting from the Local Group of galaxies within 5 Mpc, out to $z \sim 0.1$. Traditional and new probes will be shown to support the standard paradigm of structure formation, but not without raising a few eyebrows. Mild tweaks will be discussed as well as potential constraints on alternative theories of gravity.

Oeckl Robert (CCM-UNAM)

Quantum Gravity and the Foundations of Quantum Theory

Starting from the guiding principles of spacetime locality and operationalism, we consider a general framework for a probabilistic description of nature. Crucially, no notion of time or metric is assumed, neither any specific physical model. Remarkably, the emerging framework converges with a recently proposed formulation of quantum theory [1], obtained constructively from known quantum physics.

A quantum field theory for the atoms of space

We give a brief introduction to the group field theory (GFT) formalism for quantum gravity, a 2nd quantised reformulation of loop quantum gravity and spin foam models and a group-theoretic enrichment of the purely combinatorial tensor models. We then review some recent key developments concerning: the definition and analysis of 4d gravity models, progress in GFT renormalisation, and the extraction of effective cosmological dynamics from GFT condensates.

Padilla Antonio (UoN)

Sequestering the Standard Model Vacuum Energy

This talk is based on [1, 2]. We propose a very simple reformulation of General Relativity, which completely sequesters from gravity all of the vacuum energy from a matter sector, including all loop corrections and renders all contributions from phase transitions automatically small. The idea is to make the dimensional parameters in the matter sector functionals of the 4-volume element of the universe. For them to be nonzero, the universe should be finite in spacetime. If this matter is the Standard Model of particle physics, our mechanism prevents any of its vacuum energy, classical or quantum, from sourcing the curvature of the universe. The mechanism is consistent with the large hierarchy between the Planck scale, electroweak scale and curvature scale, and early universe cosmology, including inflation. Consequences of our proposal are that the vacuum curvature of an old and large universe is not zero, but very small, that $\omega_{\text{BE}} \approx -1$ is a transient, and that the universe will collapse in the future.

Global status of neutrino oscillations

I will present the current status of the global neutrino data analysis, pointing out its unique role in constraining the two crucial (still) unknown parameters: the CP-violating phase $\delta$ and the $\theta_{23}$ octant. In this context, I will discuss the slight overall preference for $\theta_{23}$ in the first octant and for non-zero CP violation with $\sin \delta < 0$. The (in-)stability of such intriguing indications within different combinations of data sets will be considered in detail. Finally, I will discuss the robustness of the 3-flavor analysis in the presence of new light sterile neutrinos, whose existence is suggested by very-short-baseline experiments and cosmological data.

Patella Agostino (CERN)

Lattice gauge theories beyond QCD

As the number of flavours in QCD is increased beyond some threshold, chiral symmetry is restored and long-distance physics becomes scale invariant. The region of parameter space in which this happens is called “conformal window”. The phenomenology of theories in the conformal window or close to it is very different from real-world QCD, and clearly shows how rich gauge theories can be. Near-conformal gauge theories have been conjectured to be viable models for physics beyond the Standard Model, and as they might naturally incorporate a Higgs-like scalar, and in this sense they are very different from traditional technicolor theories. As these theories are inherently non-perturbative, lattice simulation provide a unique setup to investigate them from first principles. In this talk I will review the main results and open questions in this field, the challenges ahead, and the techniques used.
Relativistic outflows from compact objects and generation of Astroparticles

The relativistic ejections of plasmas from black hole environments and pulsars lead to the production of high energy radiations and cosmic rays, possibly ultra high energy cosmic rays up to a few 10^20 eV, through a special kind of shocks. A special kind of self-sustaining, nonlinear structure, called collisionless relativistic shock, will be presented, which is considered as explaining the high energy phenomena as the interplay of a front made of an electromagnetic barrier, the generation of a very intense magnetic turbulence and the generation of a population of high energy particles. Numerical simulations, theoretical developments and possible experiments at powerful laser facilities of these relativistic collisionless shocks have stimulated a significant progress in high energy astrophysics nowadays.

Looking for the first star-forming galaxies in the universe

The presentation will be focused on the discussion of the latest results regarding the identification and study of the first star-forming galaxies in the universe, and the constraints derived from these studies on the reionization.

Perez Alejandro (CPT)
Black hole entropy and entanglement of Planckian degrees of freedom

We analyze the relationship between entanglement (or geometric) entropy with statistical mechanical entropy of horizon degrees of freedom when described in the framework of isolated horizons in loop quantum gravity. We show that, once the relevant degrees of freedom are identified, the two notions coincide. The key ingredient linking the two notions is the structure of quantum geometry at Planck scale implied by loop quantum gravity, where correlations between the inside and outside of the black hole are mediated by eigenstates of the horizon area operator.

Piazza Federico (APC)
Dark Energy phenomenology: the effective field theory approach

The discovery of the accelerating expansion of the Universe is motivating an impressive amount of theoretical and observational activity. I will focus on recent and ongoing works that aim at a unifying description of dark energy and modified gravity models containing a scalar degree of freedom in addition to general relativity. Such an effective field theory approach allows, on the one hand, a transparent analysis of the possible theoretical mechanisms at the basis of dark energy; moreover, it provides a useful set of parameters that can be efficiently constrained with observations. I will show the present observational constraints based on the growth rate of cosmic structures and the forecasts for future surveys such as EUCLID.

Pinamonti Nicola (Univ. of Genova)
Influence of quantum matter fluctuations on the expansion parameter of timelike geodesics

During this talk, we shall discuss the passive influence of quantum matter fluctuations on the expansion parameter of a congruence of timelike geodesics in a semiclassical regime. In particular, we shall see that the perturbations of this parameter can be considered to be elements of the algebra of matter fields at all perturbative order. Hence, once a quantum state for matter is chosen, it is possible to explicitly evaluate the amplitude of the geometric fluctuations. After introducing the formalism necessary to treat similar problems, we estimate the approximated probability of having a geodesic collapse in a flat spacetime due to those fluctuations. Starting from this, some estimate of the spacetime uncertainty relations will be given.

Status of the BSM scenarios

The two main messages from the LHC, after its first phase, are the discovery of the Higgs-like particle and no evidence for any BSM physics. This stunning, continuous, success of the SM up to the mass scales of order 0(1 TeV) is very puzzling. Although with the discovery of the Higgs particle, the SM is a consistent theory that can be extrapolated up to the Planck scale, it leaves unanswered several well known experimental and theoretical questions. In particular, the naturalness of the weak scale as the guiding principle for BSM physics is now somewhat challenged. From the historical perspective, the concept of naturalness in particle physics is a crucial issue and it should not be abandoned too quickly. After the lessons from the LHC, supersymmetry still remains to be the leading candidate for BSM physics. Other BSM scenarios and the near term experimental prospects for discovering supersymmetric or non-supersymmetric BSM physics will also be briefly reviewed.

Origin of Cosmic Rays

Brief overview of the current status and prospects of cosmic ray studies is presented. Our Galaxy and extra-galactic space are filled with cosmic rays, a relativistic gas of high-energy protons, electrons, and heavy nuclei. The directly measured cosmic ray energy spectrum extends from about 1 MeV to energies above $10^{20}$ eV. The radio-astronomical, X-ray, gamma-ray and the first very high energy neutrino observations shed light on the origin of cosmic rays. The model of cosmic ray origin in supernova remnants (including pulsars), the interpretation of Voyager data on low energy particles, the structure of knee in cosmic ray spectrum at $3 \times 10^{15}$ eV, and the energy limit of Galactic sources are discussed. The origin of cosmic rays with energies above $10^{17}$ to $10^{18}$ eV may be associated with the Active Galactic Nuclei, the progenitors of Gamma-Ray Bursts, the fast spinning newborn pulsars, the large-scale structure formation shocks and some other objects.

The effects of assembly bias on galaxy clustering predictions

This talk is based on [1]. The HOD model is frequently used in surveys to predict the mass of the dark matter haloes from the clustering of galaxies. On the other hand, semi-analytical models of galaxy formation are often used to populate simulations according to some physical prescriptions and merger trees. We use the Millennium Simulation with their semi-analytical models of galaxy formation to reconstruct the galaxy bias from the halo bias assuming the HOD model in order to study the compatibility of the HOD model in these galaxy catalogues. We find that assembly bias affects the reconstructions for low masses.

July, 16, 11h00 – 11h45, Amphi “Massiani”, Plenary Session 3

Hawking radiation in loop quantum gravity

We exploit the recently found exact solution of the quantum constraints of loop quantum gravity in vacuum with spherical symmetry to analyze a quantum field theory living on the quantum space time. The main effect of the quantum background is to lead to field equations that are discrete for the quantum field theory. The Hartle-Hawking, Unruh and Boulware vacua are all recovered with small modifications, but the discrete structure eliminates all infinities associated with physical quantities computed on the vacuum. We also briefly address the issue of Lorentz invariance and the emergence of limitations on the matter content of the theory.

Constraints on BSM physics through the Higgs couplings

We will discuss the implications from the measured mass and production/decay rates of the observed Higgs boson on several well motivated extensions of the Standard Model.

Firstly, we will show that in the Minimal Supersymmetric Standard Model, to a good approximation, the phenomenology of the lighter Higgs state can be described by its mass and three couplings: those to massive gauge bosons and to top and bottom quarks. We will then demonstrate that the value $M_0 \approx 125$ GeV together with the non-observation of superparticles at the LHC, indicates that the SUSY-breaking scale $M_0$ is rather high, $M_0 > 1$ TeV, leading to a Higgs sector that can be described, to a good approximation, by only two free parameters.

Secondly, we will discuss how the LHC limits on the invisible Higgs branching fraction impose strong constraints on Higgs portal models of dark matter.
Ramazanov Sabir (ULB)  
July, 16, 16h10 – 16h30, Amphi "Charve", Cosmology

Probing primordial statistical anisotropy with WMAP and Planck data

We constrain several models of the early Universe that predict statistical anisotropy of the cosmic microwave background (CMB) sky. We make use of WMAP9 and Planck maps deconvolved with beam asymmetries. As compared to previous releases of CMB data, they do not exhibit the anomalously large quadrupole of statistical anisotropy. This allows to strengthen the limits on the parameters of models established earlier in the literature. Among the others, we discuss constraints on the class of models with the Maxwellian term non-minimally coupled to the inflaton and a row of alternatives to inflation, i.e., Galilean genesis and conformal rolling scenario. The talk is based on the results obtained in the papers [1,2,3].

Perturbative algebraic QFT as a universal framework for constructing physically motivated models in quantum field theory

Perturbative algebraic quantum field theory is a formalism which allows to put perturbative QFT on a solid mathematical basis and solves many conceptual problems. It has proven to be a very successful framework for QFT on curved spacetimes, since it allows to separate the algebraic structure of the theory from the construction of a state. The main idea, inspired by the Haag-Kastler axiomatic framework, is to define a model of a QFT by giving a net of unital $*$-algebras, assigned to regions of spacetime. To construct such a model, one starts with a free classical theory, then obtains the free quantum theory via deformation quantization and finally introduces the interaction by means of Epstein-Glaser renormalization. In this overview talk I will show how this method works in particular examples and I will report on recent results.
Constructive Identities for Physics

In his classical paper "On Sense and Reference" [1] Frege asks: In which sense the Morning Star (MS) and the Evening Star (ES) are the same planet Venus? As Frege observes the assertion of identity MS=ES unlike the assertion of identity MS=MS (or MS=MorningStar) has empirical content and in this respect is not trivial. So it is unclear how the same notion of identity may apply in these two very different cases. Frege solves the problem by distinguishing between the sense and the reference of a given linguistic expression: although sentences MS=MS and MS=ES have the same reference "true" they still have different senses (i.e., different meaning).

Notice that Frege’s example is not purely linguistic: in his time similar questions concerning identities of some comets and asteroids remained open; in today’s astronomy the identification of new astronomical sources is never given for free but always has a complicated procedural character. Although Frege managed to explain how the identity MS=ES can hold in principle, his theory of identity provides no clue to how this or any other identity occurring in empirical sciences can be possibly grounded and justified. Since Frege’s theory does not take the issue of empirical justification into account it remains largely irrelevant to the practice of empirical sciences. Given that the naive pretheoretical understanding of identity proves insufficient at least in some areas of the modern science (think about the particle physics) the need of a new formal approach to identity in physics and other empirical sciences seems me obvious.

In this paper I develop a constructive approach to identity in physics based on Martin-Löf’s Constructive Type theory [2] and Voevodsky’s Homotopy Type theory [3]. While earlier attempts to modify the classical identity were mostly motivated by the idea of its ‘weakening’ (as in the case of Krause’s theory of quasi-sets, for example), the Homotopy Type theory allows for a view on identity as a construction from available empirical data and theoretical predictions/retrodictions. Suppose after Frege that identities of MS and ES are somehow fixed beforehand. This means that one is in a position to identify two independent observations of MS as observations of one and the same object; similarly for ES. In Martin-Löf’s theory such presupposed identities are called definitional, while the non-trivial identity MS=ES counts as propositional. In order to establish proposition MS=ES one uses available observational data (along with a theory allowing for predictions and retrodictions of future and past positions positions of celestial bodies) and reconstructs a continuous path (trajectory) from MS to ES. In the classical celestial mechanics such a continuous trajectory indeed qualifies as the wanted identity proof, namely, as the wanted evidence of the fact that MS and ES is in fact one and the same planet continuously moving from its morning position to its evening position.

Modern physics provides contexts where such ‘identity paths’ are multiple and support non-trivial homotopic structures. Two obvious examples are gravitational lensing and Feynman path integrals (interpreted in terms of multiple paths of the same particle). In both these cases the identification (of sources and particles correspondingly) involves not only paths but also their homotopies (i.e. ‘paths between paths’ or ‘2-paths’). Thus in these cases the 2nd order identities (in the sense of Martin-Löf’s theory) also acquire a physical meaning. Whether still higher-order identities may equally have some physical meaning remains a research question. A recent work by Schreiber [4] where higher-order identities are understood as gauge transformations suggests the answer in positive. Pushing this line one may tentatively consider the Homotopy type theory as a general logico-mathematical framework for representing physical objects: in this framework objects are represented by higher-order homotopy groupoids, which determine the objects’ identity types and also their topological properties.

Tentative applications of higher identity types in empirical contexts help one to clarify the distinction between the definitional and the propositional identity Martin-Löf’s theory from an epistemological standpoint. Admittedly one cannot proceed a scientific reasoning without taking some notion of identity for granted. In Martin-Löf’s theory this role is played by the definitional identity. However there is no reason to consider the definitional identity as fundamental. We treat the identity MS=MorningStar as definitional simply because we have decided (after Frege) not to analyze the way in which different phenomena observed at different times by different people are identified as observations of the same Morning Star. In a different context the non-trivial empirical character of this identity can be similarly taken into account. Thus a definitional identity has the character of explicit assumption (that can be questioned and analyzed if needed) rather than that of ultimate foundation.

References

Quantization, spatiotemporalization and pure variation

Understand the intrinsic physical meaning of quantum formalism leads ontologically to admit that one fundamental side of reality is purely contradictory, irreducibly random, objectively indeterminate and intrinsically independent of relativistic space-time. It means also that physical reality has another fundamental side, i.e. space-time, and that both are irreducible to each other. Quantum reality, discretized by the Planck constant, assume coherent states and partially ordered variables (that are commutative or not), while on the other side, relativistic space-time, structured by the speed of light, assume coherent variables and partially ordered states (that are causally related or not).

From this point of view, fields would be only a derived mixture of these two sides. But quantum reality and relativistic space-time seem to be mixed in two kinds of fields themselves irreducible to each other. If, on one hand, quantum field theory has already formalized the way that quantum reality locates, evolves and interacts on a relativistic background, on the other hand, quantum gravity tends to formalize the way that smooth and causally ordered space-time emerges on a quantum background. But no unification of the two fundamental sides of reality must be waited at this derived level. Unification could perhaps intervene only upstream, in a pure variation preceding and underlying its double distinction in variables and states of variation, i.e. its quantization or its localization and their derived mixtures.

Rouan Daniel (LESIA) Soon 20 years of “La Main à La Pâte”, an international model for inquiry-based science education in elementary school

I’ll present the status and the achievements of La Main à La Pâte, an international model for inquiry-based science education in elementary schools developed in France since 1995, under the impulse of Nobel prize Georges Charpak and Académie des Sciences. The pedagogical approach is based on study of objects of the real world, with science as an inquiry. Emphasis is put on: Questioning, Autonomy, Experimenting, Collective construction of knowledge. An important aspect of our action is the development of international partnerships, with for instance websites in six languages. I’ll also present the new program Maisons pour la science started in France to insure the professional development of teachers in science.

Rovelli Carlo (CPT) Loop Quantum Gravity

I give a general overview of the developments in Loop Quantum Gravity and I describe a recent idea for a possible novel window of observation of quantum gravitational phenomena: Planck stars.

Rudolph Alexander (Cal Poly Pomona) Introduction of interactive learning into French university physics classrooms

We report on a project to introduce interactive learning strategies (ILS) to physics classes at the Université Pierre et Marie Curie (UPMC), one of the leading science universities in France. In Spring 2012, instructors in two large introductory classes, first-year, second-semester mechanics, and second-year introductory E&M, enrolling approximately 500 and 250 students respectively, introduced ILS into some, but not all of the sections of each class. Pre- and post-instruction assessments (FCI and CSEM respectively) were given, along with a series of demographics questions. Since not all lecture or recitation sections in these classes used ILS, we were able to compare the results of the FCI and CSEM between interactive and non-interactive classes taught simultaneously with the same curriculum. We also analyzed final exam results, as well as the results of student and instructor attitude surveys between classes.

Our results show that ILS are effective at improving student learning by all measures used: research-validated concept inventories and final exam scores, on both conceptual and traditional problem-solving questions. Multiple Linear Regression analysis reveals that interactivity in the classroom is a significant predictor of student learning, showing a similar or stronger relationship with student learning than such ascribed characteristics as parents’ education, and achieved characteristics such as GPA and hours studied per week. Analysis of student and instructors attitudes shows that both groups believe that ILS improve student learning in the physics classroom, and increases student engagement and motivation. All of the instructors who used ILS in this study plan to continue its use.

This work is based on our paper which was published recently in Physical Review Special Topics - Physics Education Research; it was an editor’s suggestion when it came out: http://journals.aps.org/prstper/issues/10/1

Ryu Chang-Mo (POSTECH) Design and build physics lab course for general physics program in college

A new type of general physics experimental lab in a college, learning physics principles via designing and building a device has been attempted at POSTECH in Korea. Since 2010. Traditional general physics experiment course, which is almost standardized all over the world, is based on the concept to confirm and verify in the real world the principles taught in the class. The design and build physics lab (DBL) normally provided in the second semester emphasizes students to learn and realize themselves how physics principles operate in a real product by working on a project as a team, in agreement with the spirit of the STEAM educational system. In this paper, our experience on this new teaching approach in Korea in the past few years will be presented.
Magnetic field generated by the Weibel instability
The origin of the magnetic field in the universe is of great interest. Biermann's battery and the Weibel instability have been considered as candidates for such mechanisms [1]. The Weibel instability is believed to play an important role in the Super Nova remnant (SNR) and in the inertial fusion plasma. In this paper, we discuss the evolution of current structures and magnetic fields of the nonlinear Weibel instability up to the saturation regime, based on PIC simulation results.

SUSY after LHC run 1
The successful data taking of the LHC experiments during run 1 allowed already for a detailed investigation of possible models with underlying supersymmetry as well as for the discovery of a Higgs boson. In this talk, the status of the experimental results will be briefly summarized and implications of the findings of LHC run 1 for viable models based on supersymmetry will be discussed. Constraints from direct searches as well as from indirect measurements, in particular the Higgs boson mass, will be taken into account.

The extragalactic sky in the Fermi era
Since its launch by NASA in June 2008, the Fermi satellite has opened a new window on the gamma-ray sky. On-board Fermi, the Large Area Telescope (LAT) detect photons with an energy from 20 MeV to more than 300 GeV. After almost 6 years of monitoring of the sky, the LAT has increased our knowledge of the extragalactic sky with unexpected and spectacular discoveries like the Cen A Lobes, a detailed measurement of the EBL and more. In this talk, the review of the most important results in the extragalactic sky of the last 6 years will be made as well as what can be expected for the future.

Review of neutrinoless double beta decay search
The observation of a neutrinoless double beta decay would be the proof that the neutrino is a Majorana particle, identical to its own anti-particle, and would correspond to a process violating the lepton number. In this talk, I will give a review of the various experiments which are searching for a neutrinoless double beta decay.

Discovering dark matter
Much effort has been devoted to the study of weak scale particles, e.g. supersymmetric neutralinos, which have a relic abundance from thermal equilibrium in the early universe matching that of the dark matter. This does not however provide any connection to the comparable abundance of asymmetric baryons, which must have a non-thermal origin. 'Dark baryons' from a hidden sector with a similar asymmetry and mass of $\mathcal{O}(5)$ GeV would naturally provide the dark matter. Low-threshold direct detection experiments are required to find such particles, while monojet searches at colliders provide a complementary probe.

Galactic foregrounds for the CMB
We find imprints of galactic structures viz. the 'radio loops'[1] in the derived maps of the cosmic microwave background, even at microwave frequencies where emission by dust dominates [2]. The emission mechanism may be magnetic dipole radiation from dust grains enriched by metallic iron, or ferrimagnetic molecules [3]. This new foreground is present at high galactic latitudes, in particular in theBICEP2 observational window, and potentially dominates over the expected B-mode polarisation signal due to primordial gravitational waves from inflation.

Black holes in Asymptotically Safe Gravity

Black holes are probably among the most fascinating objects populating our universe. Their characteristic features, encompassing spacetime singularities, event horizons, and black hole thermodynamics, provide a rich testing ground for quantum gravity ideas. In this talk, we review the status of black holes within Weinberg’s asymptotic safety program [1].

The resulting quantum improved Schwarzschild black hole is discussed in detail and the effective geometry will be compared to recent findings within Loop Quantum Gravity [2]. Moreover the quantum singularity emerging for the inclusion of a cosmological constant [3] is elucidated and linked to the phenomenon of a dynamical dimensional reduction of spacetime.

Particle like solutions in modified gravity: the Higgs monopoles

This talk is based on [1]. Plethora of inflationary models based on modified gravity have been built in last decades and first experimental probes seem to appear in favor of the inflationary paradigm.

In this talk, I will focus on one of them, the Higgs inflation [2], and show the combined constraints required for such a model at cosmological and gravitational scales, i.e. for compact objects. In particular, I will show that Higgs inflation model gives rise to particellelike solutions around compact objects, dubbed Higgs monopoles, characterized by the nonminimal coupling parameter, the mass and the compactness of the object. For large values of the nonminimal coupling, forbidden compactnesses appear.

The role of BRST charge as a generator of gauge transformations in quantization of gauge theories and Gravity

In the Batalin-Fradkin-Vilkovisky (BFV) approach to quantization of gauge theories a principal role is given to the BRST charge which can be constructed as a series in Grassmannian (ghost) variables with coefficients given by generalized structure functions of constraints algebra. Alternatively, the BRST charge can be derived making use of the Noether theorem and global BRST invariance of the effective action. In the case of Yang - Mills fields the both methods lead to the same expression for the BRST charge, but it is not valid in the case of General Relativity. It is illustrated by examples of an isotropic cosmological model as well as by spherically-symmetric gravitational model which imitates the full theory of gravity much better. The consideration is based on Hamiltonian formulation of General Relativity in extended phase space (1, 2).

At the quantum level the structure of the BRST charge is of great importance since BRST invariant quantum states are believed to be physical states. Thus, the definition of the BRST charge at the classical level is inseparably related to our attempts to find a true way to quantize Gravity.

A Test Bed for High Energy Physiscs

We briefly comment upon the parallel between graphene and high energy fermions and explore the possibility of using the former as a test bed for the latter rather like Reynold’s numbers in a wind tunnel. We also point out that there are parallels to Quantum Gravity approaches, which indeed provide a novel explanation for such effects as the FQAE.
Issues in Galaxy Formation 2014

The origin of the galaxies represents an important focus of current cosmological research, both observational and theoretical. Its resolution involves a comprehensive understanding of star formation and evolution, galaxy dynamics, supermassive black holes, and the cosmology of the very early universe. I will review our current understanding of galaxy formation and describe some of the challenges that lie ahead. Specific issues that I will address include the star formation rate in galaxies and the galaxy luminosity function, including the role of feedback.

Sinitsyna Vera Georgievna (FIAN RAS) July, 18, 17h40 – 18h00, Amphi "Charve", Astroparticle Physics

Very high energy gamma-emission of Perseus Cluster

The cluster of galaxies in Perseus have long been considered as possible candidates for the sources of high and very high energy γ-ray emission generated by various mechanisms. We presented the results of fifteen-year-long observations of the central galaxy in the cluster NGC 1275 at energies 800 GeV-40 TeV discovered by the SHALON telescope in 1996 [1,2,3]. The data obtained at very high energies, namely the images of the galaxy and its surroundings, and the flux variability indicate that the TeV γ-ray emission is produced by a number of processes: a part of this emission is generated by relativistic jets in the nucleus of NGC 1275 itself. Whereas, the presence of an extended structure around NGC 1275 [3] is evidence of the interaction of cosmic rays and magnetic fields generated in the jets at the galactic center with the gas of the Perseus cluster.

Long-term studies of the Cygnus Region and its objects

Cygnus Region contains the number of powerful sources of radio and X-rays which are supposed as a potential TeV-emitting objects. The results of 17-year observations of the Cyg X-3 at energies 0.8 - 85 TeV, detected by the SHALON telescope in 1995 are presented [1,2,3]. A number of high activity period of Cyg X-3 were detected with SHALON during all period of observation. The significant increases of flux are correlated with flaring activity at lower energy range of X-ray and/or at observations of Fermi LAT. Also, we present the results of long-term observations of the Cygnus region which are revealed the γ-ray emission from the one of nearby object - γCyg SNR [3], placed at 2◦ from Cyg X-3. The results of γCyg SNR observation by SHALON [3] are presented with spectral energy distribution, images and integral spectra at energies 0.8 - 50 TeV.

A No Go Theorem for Gallileon like “Odd P-Forms”

We explore the possibility for generalized gauge invariant p-form theories on flat space-time. ‘Galileons’ are a well known example of scalar fields (0-form) that has non-linear extension of the second derivative terms in field equations. We prove that there is an obstruction to extending to non-linear order in the second derivatives for gauge invariant p-forms when p is odd. That is the equations of motion for the p-form field are at most linear in the second derivative of the field.

Solar wind test of the de Broglie-Proca’s massive photon with Cluster multi-spacecraft data

The exam of the literature on the large-scale astrophysical limits for the photon mass inspires a critical attitude and prompts to question whether these limits are nothing more than the outcome of idealized models. This view is confirmed by Goldhaber and Nieto [1] who state “Quoted photon-mass limits have at times been overly optimistic in the strengths of their characterizations. This is perhaps due to the temptation to assert too strongly something one ‘knows’ to be true. A look at the summary of the Particle Data Group […] hints at this.”

We use spacecraft data in the solar wind at 1 AU to estimate the mass upper limit of the de Broglie-Proca’s photon, by looking for deviations from the Ampère’s law. We take advantage of the Cluster spacecraft which both allow the direct computation of $\nabla \times \vec{B}$ from simultaneous four-point measurements of the magnetic field and provide measurements of particle currents. We estimate the upper bound for the mass $m_\gamma$ to be $1.4 \times 10^{-49}$ kg without using any ad hoc model. Finally, we discuss how this limit can be lowered and compare with currently accepted values in the solar wind.

The Signature of Low Redshift Large-Scale Structure in the Cosmic Microwave Background

As microwave background photons propagate from the surface of last scatter to our telescopes, they are affected by four distinct processes in the low redshift universe: gravitational lensing, the thermal Sunyaev-Zeldovich (tSZ) effect, the kinematic Sunyaev Zeldovich (kSZ) effect and the intervening Sachs Wolfe effect (ISW). This talk will focus on the kSZ and ISW effect. I will discuss the cross-correlations between the large-scale distribution of galaxies and these two effects and show how current and future measurements can be used to probe the growth rate of structure and gravitational physics on large-scales.

Status of HEP after the LHC Run 1

In the past 20 years, the Standard Model (SM) of elementary particles and their interactions has provided an unfailing and remarkably accurate description of all experiments with and without high-energy accelerators, establishing that we understand the physics of the very small up to energy scales of 100 GeV. The Large Hadron Collider of CERN, and its experiments, were conceived to probe the physics of the next frontier, that of the TeV energy scale. True to their charge, the experiments have delivered hundreds of significant and often beautiful measurements, along with the discovery of what looks like the first fundamental scalar particle. The triumph of the Standard Model is complete, especially since no new signal has emerged from the intense searches for “new physics” — yet. The field is now at a crossroads: the existence of a Higgs boson opens a new set of questions, while the evidence, both direct and indirect, that there physics beyond the SM does exist, is still strong and convincing. The talk will present a broad-brush picture of how Run 1 of the LHC has shaped the field of High Energy Physics; along with why expectations are still so very high.

July, 18, 09h30 – 10h00, Amphi "Sciences Naturelles", Plenary Session

It Ain’t Necessarily So: Interpretations and Misinterpretations of Quantum Theory

The traditional view is that a theory is a conceptual framework providing predictions, and the results of experiments or observations decide whether the theory is right or wrong. It will be contrasted with the modern view that one must incorporate the conditions of applicability of a concept into the very meaning of the concept (measurability analysis), and that only a series of theories (scientific research program) can be said to be scientific or unscientific. This modern view will be applied to a number of questions in quantum mechanics (what is quantization? states vs processes, open vs closed systems) and quantum field theory (particles and field quanta, bosons vs fermions), and to the search for a theory of quantum gravity (background independent vs fixed background theories).

Stachel John (CES)  
July, 17, 14h30 – 15h05, Room 408, Epistemology and Philosophy

Do Quanta Need a New Logic?

What is Logic? My answer consists of three steps: Logic is about Language, Language is about the World. Panlogism is the attempt to “short circuit” this process by identifying the real object and the “concrete-in-thought.” It leads to the assertion: Logic is about the World. If we abandon panlogism, we see that quantum logics (note the plural!) are just different ways of reformulating the same content. The danger: is that, If we accept the idea of one unique quantum logic, that provides all the answers, this prevents us from confronting the real questions about quantum mechanics.
Investigating inflation and super-high-energy physics with new CMB data

The measurement of a small deviation of the primordial spectrum of scalar (density) perturbations in the Universe from the exactly flat (Harrison-Zeldovich, $n_s = 1$) one in the WMAP and Planck CMB experiments confirms the general prediction of the early Universe scenario with the de Sitter (inflationary) stage preceding the radiation dominated stage (the hot Big Bang) and strongly restricts the class of viable inflationary models [1]. Thus, the status of the inflationary paradigm is changing from "proving" it in general and testing some of its simplest models to applying it for investigation of the actual history of the Universe in the remote past and particle physics at super-high energies using actual observational data. The announced discovery of primordial gravitational wave background through the measurement of the B-mode of the CMB linear polarization in the range of multipoles $\ell = 50 - 150$ in the BISEP2 experiment [2] confirms another general prediction [3] of this scenario, as well as produces the direct evidence for the existence of a very strongly curved space-time with $H \sim 10^{-5} M_{Pl}$ in the past of our Universe and the necessity of quantization of gravitational waves. Still the BISEP2 result is partially contaminated by foregrounds (mainly by polarized galactic dust emission) and requires confirmation of its blackbody character. Moreover, comparison of BISEP2 data with the temperature and E-mode polarization data earlier obtained in the WMAP and Planck experiments shows that the inflationary stage is not so simple and may not be described by a one-parametric model. In particular, the primordial spectrum of scalar perturbations generated during inflation is not of a power-law form [4], mainly due to the $\sim 10\%$ depression of the angular anisotropy power spectrum in the multipole range $\ell = 20 - 40$. A class of models describing this feature which implies existence of some scale (i.e. new physics) during inflation is proposed [5]. Furthermore, account of additional wiggles in the spectrum at $\ell \approx 22$ and $\ell \approx 40$ requires further complication of the inflaton potential [6] by introducing sharp features of the type suggested by previous studies [7]. While viable inflationary models with a smooth potential require the inflaton mass $m \sim 10^{13}$ GeV, it has to increase up to $H \sim 10^{15}$ GeV and may be larger near the feature. Thus, combination of CMB temperature anisotropy and polarization data helps to make a "tomographic" study of inflation and particle physics in this range of energies.

Upper secondary students face optic diffraction using simple experiments and on-line measurements

The phenomenon of optical diffraction is crucial in order to recognize the wave behavior of light [1]. It limits the resolving power of optical instruments, including the human eye. Therefore it is of fundamental importance not only for practical applications, for example as in microscopy, but also in ability of our eye to distinguish two objects, as well as in our perception of one colors next to another, aspect exploited for example by Pointillists painters.[2]

The exploration of the optical diffraction in didactic laboratory with on-line sensors offers a unique opportunity to high school students to have experience of this important phenomenological context. Activities of computer modeling allow to pass from phenomenology to its interpretation. [3-5]

A research-based path was developed for upper secondary school approaching the optical diffraction through the experimental exploration of the diffraction pattern produced by a laser beam incident on a single slit. Students first analyze the diffraction pattern qualitatively, recognizing the global properties, then measuring with on-line sensors the light intensity vs position, constructing empirical relations between order and position of minimum, order and position of maximum, position and intensity of maximum. A computer modeling, based on Huygens’ principle, is used to fit experimental data, showing the empirical relations, characterizing the experimental distribution and that obtained with the model. [3, 6]

Experiments in school was performed with 85 students, using IBL tutorial worksheets e pre-test, post-test. Positive learning paths of students emerged concerning the role of diffraction in everyday situations, activated by the qualitative analysis of the global properties of the diffraction pattern. The characteristic properties of the diffraction pattern, explored with on-line sensors, combined with the modeling activities aided students to move from a geometric point of view, based on rectilinear rays, to a physical one, based on an interference / intensity analysis.

Probing non-standard gravity with the growth index of cosmological perturbations

This talk is based on [1]. The growth index of cosmological perturbations is one of the most performant probes of the nature of Dark Energy (DE), the mysterious mechanism driving the late epoch acceleration of the universe. At variance with classical geometrical observables, such as distances, which only probe the background sector of a cosmological model, this observable provides insight into first order dynamical effects, and it is therefore a key test for modified gravity scenarios often invoked to explain away the DE issue.

In this talk I will first show how the whole information about the growth rate history of linear cosmic structures can be precisely encoded into a small set of growth index parameters whose amplitude can be analytically predicted by theory. Then I will go on demonstrating how these parameters naturally define a space where theoretical predictions can be compared against data in a model independent way. Finally [2], by exploiting the Effective Field Theory of dark energy, a formalism which describes virtually all the gravitational theories containing a single scalar degree of freedom in addition to the metric, I will explore which alternative cosmological scenarios are not in conflict with current growth data.

References
Model building in almost-commutative geometry

Alain Connes’ noncommutative geometry allows to unify the classical Yang-Mills-Higgs theory and General relativity in a single geometrical framework, so called almost-commutative geometries. This unification implies restrictions for the couplings of the Standard Model at a given cut-off energy which reduce the degrees of freedom compared to the classical Standard Model.

I will give an introduction to the basic ideas of almost-commutative model building and present models beyond the Standard Model that may be phenomenologically interesting. These models include extensions of the fermionic and the gauge sector as well as extensions of the scalar sector.

ALICE results in p–Pb collisions at the LHC

ALICE studies the properties of the strongly interacting matter at the extreme energy densities reached in heavy-ion collisions at the LHC. In this context, the measurements in proton-proton and proton-nucleon collisions are mandatory: the former sets the reference, while the latter provides further insight into the effects due to cold nuclear matter, which is crucial in the understanding of heavy-ion collisions. In this talk, a selection of the recent results in p–Pb collisions at the LHC will be presented.

Sverdlov Roman (IISER)

Describing many-particle QM as well as QFT in terms of “single particle” QM with one extra dimension

From ontological point of view, single particle QM makes a lot more sense than multiparticle case. After all, in case of a single particle you can claim that \( \psi \) is NOT “probability amplitude” but, rather, it is simply “classical field”; it simply HAPPENS that probability of collapse of \( \psi \) coincides with the square of its absolute value. On the other hand, in case of many particles you can not make this argument: after all, classical field lives in ordinary space, NOT in configuration space! Motivated by this, I am attempting to reduce multiparticle quantum mechanics to single particle one. I am doing this by the following trick. First, I introduce extra dimension. Then I design various “classical” objects in such a way that we have different “classical” configurations on different \( x^5 = \text{const} \) hyperplane. Finally, we introduce one SINGLE quantum particle, the one referred to as “pointer”, and the “pointer” takes the classical configuration from the hyperplane it resides on and makes it “come true”. Thus, instead of quantizing configurations, all we have to do is quantize the location of a pointer, which reduces multiparticle QM to single particle QM. This approach is also extended to reducing quantum field theory to single particle quantum mechanics, as well; we simply replace “classical particle distribution” on the hyperplanes with “field distributions”. The reference to the paper where I have done the above work is [1].

Category and Physics

I propose to begin an assessment of the debate on the intervention of the category theory in physics. 1- I begin by considering the classical relationship between geometry and physics using the example of Newton, of a formalism of the theory of GR and quantum mechanics. 2- I am going to show that categorical formulation provides numerous epistemological and philosophical benefits. I will then make a distinction between a local and a global reformulation. 2- I show why one must choose, and often develop a specific understanding of the theory categorized. The risk of the development of the theory of categories itself regardless of initial physical target is always incurred. At this level also the danger of leaving the physical out of it is always present. 4- I want to show how the risk itself is relevant for reasons both physical and mathematical. 5- I will discuss some relationships between geometrization and categorification. My analysis will focus on twistor theory.

Measurement of leptons related quantities in AMS

The first results of the AMS experiment on board the International Space Station corresponding to the first two years of data taking will be presented. A measurement of the positron fraction in primary cosmic rays in the energy range from 0.5 GeV upwards, as well as the combined and individual electrons and positrons spectra will be expounded. The main features of these analysis will be explained and some perspectives on the future of these measurements will be given.

Tartaglia Angelo (POLITO-DISAT)  
The strained state cosmology

This talk presents an interpretation of the cosmological constant and of the dark energy, in terms of deformation energy density of space-time. The latter is treated as an elastic medium, whose Lagrangian density is built of terms proportional to the lowest (in practice the second) order scalars associated to the strain tensor, i.e. the difference between the actual and the Euclidean metric tensors, and its first and second order derivatives [1]. The new Einstein equations contain an additional ‘source’ corresponding to the deformation energy density of space-time. Global symmetries may be induced by texture defects in the manifold [2]. Solutions endowed with Robertson-Walker [2], Schwarzschild and Kerr symmetries are discussed.

Bright Gamma-ray Pulsars in the Fermi Era : Results and prospects with ground-based telescopes

With more than 140 gamma-ray emitting pulsars detected, the Large Area Telescope (LAT) aboard the Fermi satellite has revolutionized the field of high-energy pulsar astronomy.

While the processes (e.g. curvature radiation, synchrotron, Inverse-Compton emission) thought to be responsible for the pulsed emission at high energies are well known, the details of the acceleration and radiation mechanisms at play are still widely debated through several models.

The analysis of the large data-set of events available from the brightest gamma-ray pulsars, six years after the launch of the Fermi satellite, reveals for these individuals a harder spectrum than previously measured (and expected) and hence increases the chance to detect them with ground-based Cherenkov Telescopes. The detection from ground at the highest energies brings in turn precious information allowing one to constrain severely existing models. The latest results will be presented, and prospects in the field will be discussed.
On the K-theoretic classification of topological phases of matter

In recent years, there has been a lot of interest in studying the topological phases of quantum matter. A K-theoretic approach was suggested by Kitaev, who produced a Periodic Table of topological insulators and superconductors [2]. We take the algebraic viewpoint, and study the gapped topological phases of free fermions through a twisted crossed product $C^*$-algebra associated to the symmetry data of the system. Allowing for projective unitary-antiunitary representations, in the sense of Wigner, as well as charge-conjugation symmetries, leads to a $\mathbb{Z}_2$-graded real twisted group $C^*$-algebra, which completely encodes all the symmetry data of a quantum system. We define two $K$-theory-type invariants of this algebra: the super-representation group classifies symmetry-compatible gapped phases, while the $K$-theoretic difference-group classifies differences between stable homotopy classes of such phases. We also provide a consistent physical interpretation of these classification groups, which appears to vary between existing treatments in the literature. Our approach generalises, to the non-commutative setting, the twisted $K$-theory approach of Freed and Moore [1]. It has the advantage of treating all symmetries on an equal footing, and powerful results from the $K$-theory of crossed products are available. We recover Kitaev’s Periodic Table as a special case, and clarify the origin of the periodicities and “dimension-shifts” in his table.

Healthy theories beyond Horndeski

I will present a new class of scalar-tensor theories that extend Horndeski theories. Despite possessing equations of motion of higher order in derivatives, their true propagating degrees of freedom obey well-behaved second-order equations and are thus free from Ostrogradski instabilities, in contrast to the standard lore. Remarkably, the covariant versions of the original galileon Lagrangians obtained by direct replacement of derivatives with covariant derivatives belong to this class of theories. These extensions of Horndeski theories exhibit an uncommon, interesting phenomenology: the scalar degree of freedom affects the speed of sound of matter, even when the latter is minimally coupled to gravity.

Co-development of conceptual understanding and critical attitude: an essential condition for physics learning

Since nearly two decades, a decline of interest in scientific studies has entailed the choice of new objectives for science teaching in many countries. To put it briefly, affective factors like motivation and the development of competencies, for instance critical analysis, have received much attention, as well as new approaches to teaching, like Inquiry Based Science Education. Although multiple learning benefits are invoked in each case, also for the future citizen, there is often, de facto, a trend toward less conceptual development and structuring, be it in teaching objectives or in students’ achievements. I will briefly discuss the risks of oversimplification and teaching rituals in physics, and the need for developing a critical stance in students. I will then discuss, based on two investigations at upper secondary or university level (hot air balloon, radio carbon dating), the idea that a competence like critical analysis should not be envisaged separately from a minimum conceptual development. The final discussion will bear on implications for teaching.

A second part of this talk will be given in a session about physics education: From a subtractive to multiplicative approach, two concept-driven interactive pathways on the selective absorption of light.

July, 18, 14h30 – 15h00, Room 407, Physics Education

From a subtractive to multiplicative approach, two concept-driven interactive pathways on the selective absorption of light

This talk will be devoted to a type of teaching strategy - concept-driven intellectual pathways, aiming at developing conceptual understanding and critical faculty in students. The examples will bear on interaction between light and matter at university level (absorption of light by pigments, liquids, the atmosphere) and will illustrate how formal simplicity main be compatible with some exigent approach linking a search for conceptual coherence and a critical analysis.

Vikman Alexander (LMU)  
July, 18, 15h00 – 15h30, Amphi "Sciences Naturelles", Cosmology

Cosmology with Mimetic Matter

This talk will be mostly based on [2]. I will discuss cosmology of the recently introduced “mimetic” modification of general relativity [1]. This modification is manifestly Weyl-invariant and can mimic practically any cosmological époque [2, 3]. In particular, this “mimetic” modification can naturally account for a part of dark matter [2, 3]. It is also possible to unify such dark matter with dark energy as it was shown, in [3]. Finally one can construct an interesting single-field model for the early universe inflation. This model has parametrically suppressed gravity waves but does not seem to produce any non-Gaussianity, moreover the usual consistency relation for the single-field inflationary models gets modified.

Experimentation of a new pedagogical method in 1st year’s teachings of physics

The teaching of physics for first year post-bac students is confronted to increasing difficulties since several years. This problem is reinforced this year in France due to a new reform of the secondary educational system. We have experienced a new pedagogical method in the cursus “préparation aux écoles d’ingénieurs polytech”, which is the first year of the Polytech engineer school of the Aix Marseille University.

The pedagogical method is a mixing between “problem based learning” and “peer instruction”. The results of the method are very encouraging.

The outline of this talk is the following :
- listing of problems encountered by students and teachers
- presentation of the new pedagogical method
- results of the first year’s experimentation

Volpe Cristina (APC) 

Recent advances in neutrino astrophysics

Neutrinos of astrophysical origin are messengers produced in stars, in explosive phenomena like core-collapse supernovae, in the accretion disks around black holes, or in the Earth’s atmosphere. Their fluxes and spectra encode information both on their sources, the environments they traverse and on key unknown neutrino properties. We will discuss the status and key open questions in our current understanding of neutrino flavour conversion in media and its impact on astrophysical observations. We will describe some of the important recent advances in the field of neutrino astrophysics.

Chameleon Cosmology Near and Far

In this talk we will explore the possibility of testing dark energy and dark matter in the laboratory and the sky. As an example we will discuss chameleon cosmology models of dark energy and consider their challenges and limitations.

Westhoff Susanne (PITT PACC) 

The Top-Quark Charge Asymmetry – Testing Strong Interactions and More

An overview of the charge asymmetry in top-antitop quark production at hadron colliders is presented. I discuss the origin of the charge asymmetry in the Standard Model and potential contributions from new physics [1,2] in the light of the enhanced asymmetry observed by the CDF collaboration at Tevatron. A measurement of the charge asymmetry at the LHC requires tailored observables, which cope with the large symmetric background [3].

High precision gravitational self-force calculations and post-Newtonian implications

This talk is based on [1,2,3]. Until less than 10 years ago, post-Newtonian (pN) analysis was the only possible systematic method for obtaining gravitational waveforms corresponding to binary inspiral. However, these were cut-off before the merger, until the recent availability of direct results from numerical relativity computations, which could include the complete merger and ring-down phase of the orbital evolution. Unfortunately these calculations are not yet of sufficient precision to strenuously test pN methods intrinsically. By contrast, the gravitational self-force approach has become capable of advancing to extremely high precision, and of thereby testing most of the various techniques used in pN calculations. Although restricted to the extreme-mass-ratio limit, self-force calculations are now able to verify both the methods and results of pN work, and even of extending it. In fact, as will be demonstrated, they now have high enough precision to be able to determine new coefficients analytically.

Loop gravity from a spinorial action

Spinors have a wide range of applications, from quantum mechanics to particle physics, quantum information and general relativity [1]. In this talk, I will argue that they are useful also for discretized gravity, and present a version of first-order Regge calculus with spinors as the fundamental configuration variables [2]. The underlying action describes a mechanical system with finitely many degrees of freedom, the system has a Hamiltonian, and local gauge symmetries. I will derive the resulting quantum theory, and explain the relation to loop quantum gravity [3].

A new theory of light and matter

A new, linear field theory of light and matter is proposed, sharpening the principle of relativity and adding four new coupled differential equations to the original four of Maxwell. The new theory, though continuous, allows only propagating pure field solutions with an integral angular momentum. These are identified with the photon. Solutions with rest-mass are necessarily charged, with a value close to the elementary charge [1]. They have a double-covering rotation in momentum space with a resulting half-integral spin and statistics, as was discussed on the basis of an earlier non-linear theory [2]. The result is that, just as was the case for de Broglie’s concept of the harmony of phases [3] which led to his famous relation and the subsequent development of quantum mechanics, it is a rigorous consideration of the principle of relativity that leads to the quantisation of light and matter.

The Matter Bounce Scenario in Loop Quantum Cosmology

The matter bounce scenario is an alternative to inflation where scale-invariant perturbations are generated in a dust-dominated contracting space-time. In the context of loop quantum cosmology, the cosmological singularity is generically resolved and replaced by a bounce; furthermore, it is possible to deterministically evolve the perturbations from the contracting branch through the quantum bounce and calculate the form of the perturbations at the onset of the expanding branch. For the matter bounce scenario in loop quantum cosmology, scale-invariant perturbations and a small tensor-to-scalar ratio are predicted [1], in agreement with the latest observations of Planck and BICEP2 [2].

Horizons in Physics Education: a network to improve the attraction of physics

The academic network HOPE - Horizons of Physics Education - has been launched for three years from October 2013 with the support of the Life Long Learning Programme of the European Union. The 71 full partners are from 31 LLP-eligible countries of the European Union; they comprise 65 academic partners and 6 non-academic partners including the European Physical Society. The consortium is further enriched by 20 associated partners including the Institute of Physics, the American Physical Society or GIREP.

With an overall aim of enhancing the impact of physics within Europe and its visibility in society, the network will research and share good practice within four themes: the factors influencing young people to choose to study physics; physics graduates' competences that enable them to contribute to the new needs of the European economy and society; the effectiveness and attractiveness of physics teaching in Europe's university physics departments and their competitiveness in the global student market; strategies for increasing the supply of well-trained physics school teachers and for developing links between university physics departments and the teaching of physics in schools.

Construction of a quantum field theory in four dimensions

We prove that the $\lambda\phi^4$ quantum field theory on noncommutative Moyal space is, in the limit of infinite noncommutativity, exactly solvable in terms of the solution of a non-linear integral equation. Surprisingly, this limit describes Schwinger functions of a Euclidean quantum field theory on standard $\mathbb{R}^4$ which satisfy the easy Osterwalder-Schrader axioms boundedness, covariance and symmetry. We prove that the decisive reflection positivity axiom is, for the 2-point function, equivalent to the question whether or not the solution of the integral equation is a Stieltjes function. The numerical solution of the integral equation leaves no doubt that this is true for coupling constants $\lambda \in [-0.39, 0].$

July, 15, 15h30 – 16h00, Amphi "Massiani", High Energy Physics

(Getting ready for) precision physics at hadron colliders

I will review recent progresses in the field of higher-order predictions at hadron colliders, with focus on the LHC. The inclusion of higher order corrections, in particular of those corrections related with QCD, is crucial in order to get accurate and reliable predictions which are needed both to validate the Standard Model of fundamental interaction and to seek for yet unknown particles, but leads to a huge growth of the computational complexity. Recent works have lead to the possibility of computing the first subleading order (Next-to-Leading Order, NLO) corrections in a fully automated manner for any process, hiding all the computational complexity to the user. For what concerns higher orders (next-to-next-to Leading Order, NNLO and beyond), the most relevant processes for LHC physics in the SM have been covered at NNLO in the last few years, with huge efforts from different groups.

Plebanski sectors of the Lorentzian 4-simplex amplitude

The spin foam model is based on a BF-type action restricted by the simplicity constraint. However, the solutions to the simplicity constraint fall into five different sectors. In [1,2] it was argued that a certain mixing of these sectors and the freedom of choosing a tetrad orientation generates undesired terms in the asymptotic of the Euclidean EPRL-model and can be cured by an additional constraint. We here show that this is also the case for the Lorentzian model. This is joint work with J. Engle.

Decoherence and the measurement problem

The problem of measurement taken at face value shows clearly that there is an inconsistency inside the quantum formalism. The phenomenon of decoherence is often presented as a solution to it. A widely debated question is to decide between two different interpretations. The first one is to consider that the decoherence process has the effect to actually project a superposed state into one of its classically interpretable component, hence doing the same job as the reduction postulate. For the second one, decoherence is only a way to show why no macroscopic superposed state can be observed and so, to explain the classical appearance of the macroscopic world, while the quantum entanglement between the system, the apparatus and the environment never disappears. In this case, explaining why only one single definite outcome is observed remains to do. We will examine arguments for and against both interpretations and will defend a position according to which the outcome that is observed is relative to the observer in close parallel to the Everett interpretation and sharing some similarities with the Rovelli’s relational interpretation, while different on important points.
ESSnuSB Neutrino Oscillation Project

The recent measurements of the last mixing angle performed by the reactor experiment in the neutrino sector enable the search for the CP violation in the leptonic sector. The next generation of neutrino experiments will require new intense neutrino beams and large detector infrastructures.

In this context, a new facility is proposed using the European Spallation Source (ESS), currently under construction in Lund (Sweden), to produce the world’s most intense neutrino beam [1] with a megaton Water Cherenkov detector installed 1000 m down in a mine at a distance of about 500 km. This detector will also extend the physics program to proton-decay, atmospheric neutrinos and astrophysics searches [2].

The weighing of layered superconductors transition energy as a possible experimental method to ascertain the Archimedes vacuum force

The main motivations and scheme of a possible experimental way to verify the interaction of vacuum energy with gravitational field are reported [1]. The experiment consists in weighing the transition energy of layered superconductors, to which the Casimir energy is expected to give a not-negligible contribution [2,3]. The expected signal is compared with the present, or near future, small-forces measurement techniques and to show that it is comparable with expected sensitivities.

Alternative Lagrangian formulations for linearized general relativity

It is well-known that there exists an analogy between Maxwell theory and linearized gravity [1]; on the basis of this analogy it has been possible to extend some results of the former to the latter [2]. On the other hand, Maxwell theory can be written as a BF-type theory [3] and due to the mentioned analogy it is natural to ask if a BF-type action for linearized gravity exists.

We give some action principles of the BF type for linearized gravity: which are based on the Maxwell BF-type action, which on-shell reduces to the well-known Fiertz-Pauli action. Furthermore, we also explore the Hamiltonian analysis of these actions.

Some remarks on time dependent parameters in physical theories

The possibility that the gravitational constant $G$ may vary with cosmological time $t$ (or with the cosmological scale factor $a(t)$) has been intensively studied for a long time [1,2]. The possibility that this also happens with the speed of light $c$ has been taken into account. We present here some important remarks on this subject. These remarks include the intensive conditions that, in order to preserve the conservation equations of physics, if $G$ varies $c$ must also vary with time. Then with $G(t)$ and $c(t)$ both varying with time the restriction is $8\pi G/c^4 = \text{constant}$. This applies to the case of a cosmological constant assumed to be a true constant. Otherwise the restriction is $8\pi G/c^2 = \text{constant}$. We also analyze some implications on physical theories.

González Diego (Cinvestav)

A gauge connection formulation of general relativity

It has been shown in Ref. [1] that general relativity with zero cosmological constant can be described as a “pure spin-connection formulation” using a gauge $SO(3, C)$ connection and a scalar density. The case of nonzero cosmological constant was developed in references [2] and [3]. These formulations, however, are either complicated or not compatible with the case of vanishing cosmological constant. In this talk I report an action principle for general relativity that involves a gauge connection, which works well with or without cosmological constant and that is much simpler.

Philosophical Introspection of scientific cosmology

This talk is based on [1]. Scientific cosmology tries to understand the Universe at large with its origin and evolution. Observational and experimental situations in cosmology do not allow us to proceed purely based on the empirical means. We examine in which sense our cosmological assumptions in fact have shaped our current cosmological worldview with consequent inevitable limits. Cosmology, as other branches of science and knowledge, is a construct of human imagination reflecting the popular belief system of the era. The question at issue deserves further philosophic discussions. In Whitehead’s words, “philosophy, in one of its functions, is the critic of cosmologies.”

Mandrin Pierre

Spin-compatible construction of a consistent quantum gravity model from minimum information

It has been shown in [1] that a quantum gravity formulation exists on the basis of quantum number conservation, the laws of thermodynamics, unspecific interactions, and locally maximizing the ratio of resulting degrees of freedom per imposed degree of freedom of the theory. A generalized form of the First Law of thermodynamics has been imposed on the boundary of space-time volumes, while no explicit microscopic quantum structure was required. From this model, Quantum Field Theory and General Relativity have been recovered as special cases. This talk presents the generalized action in terms of tetrades and shows how the action may be related to the spin of matter fields.

Conceptual Labs for operative Exploration

In the perspective of the Model of Educational Reconstruction [1], designing new educational path require to gain new information on how students face the specific subject explored. At the PERG of Udine the main steps of the new educational paths were explored with pupils engaged in Conceptual Laboratory of Operative Exploration (CLOE) in informal learning contexts, where using different monitoring tools student spontaneous ideas as well their learning paths were explored and stimulated [2-4]. In CLOE pupils discuss everyday life scenarios, recover their everyday and sensorial knowledge, as well as involve them in the challenges of explorations according to an IBL strategies. The CLOE lab are research based proposals of learning where explore how pupils build formal thinking, reflect on phenomena and construct models, reinterpret common everyday knowledge. The research focus is on the reasoning sequence, the ways in which knowledge is structured, the development of interpretative representations. [5-7] The design characteristic of the CLOE labs are presented exemplifying it in the case of the CLOE on energy.

IDIFO Teachers Formation on Modern Physics

The main fall in motivation levels with regard to scientific studies in Italy has been collaboratively answered through the national project (Scientific Degree Project—PLS). Master IDIFO is a project in this framework for in-service teacher formation, a project focused on Didactic Innovation in Physics Education and Guidance, carried out by Udine PER Unit in collaboration with 20 Italian universities. It offers educational innovation, science learning laboratories, formative orientation (problem solving) and teacher training on Modern Physics topics for in-service teachers. It implements a model for teacher training, with an aim to develop formal thinking and to relate associated connection between Computer Science-Mathematics and Physics on Modern Physics topics. The activities such as educational and experimental workshops in presence, training teachers at a distance and in presence, conducting exhibitions, designing Inquiry Based Learning materials, activities for the orientation training in physics, informal education through conceptual laboratories (CLOE) and use of ICT to overcome the conceptual nodes in physics, teaching laboratories using problem solving and Prevision-Experiment-Comparison strategies and in-depth analysis of learning processes in educational innovation are achieved.
Primeval Radiogalaxies: The key for AGN-starburst relation

Primeval ($z > 4$) radiogalaxies are privileged targets to understand the tight relation of the supermassive black hole masses with star formation (Ferrarese & Merritt, 2000). At high $z$, star formation is disentangled from the AGN emission with Herschel observations and the help of our synthesis model Pegase. Moreover the Spitzer satellite revealed an old evolved population (Rocca-Volmerange et al., 2013, MNRAS). All the ingredients to follow the relation of AGN-star formation on a large time-scale coverage are found in a variety of radiogalaxies as the HeRGE sample (Drouart et al., 2014).

Astrophysical explanation for the PAMELA/AMS-02 anomaly

Cosmic rays being Fermi accelerated by a nearby supernova remnant shock wave will create secondaries such as positrons, antiprotons and lighter nuclei, a fraction of which will be (re)accelerated to a harder component that dominates at high energies (1,2). This accounts for the rise in the positron fraction at high energies above the expectation from diffusive propagation in the Galaxy. We use the precision AMS-02 data to predict the expected rise in the antiproton fraction which will test the model (3).

EBL measurements through the TeV gamma-ray spectra of Low- and High-red shifted AGN

The detection of TeV gamma-ray sources at high red-shifts namely NGC1275 ($z = 0.0179$), Mkn421 ($z = 0.031$), Mkn501 ($z = 0.034$), Mkn180 ($z = 0.046$), 3c382 ($z = 0.0578$), 4c+31.63 ($z = 0.295$), 4c+55.17 ($z = 0.896$) and 1739+522 ($z = 1.375$) is the evidence of less average spectral density of Extragalactic Background Light and thus the less star formation rate at early evolution stage, than it is previously believed. Also, the possible explanation of the detected very high energy gamma-emission from the distant AGNi is the re-scattering of primary TeV-photons on the Dark Matter particles, so called WISP - weakly interacting slim particles. The axion-like particles has been considered to be a candidate for such weakly interacting slim particles.

Conceptions of secondary students on phenomenology of superconduction

Currently, superconductors at low cost can be used to analyze the typical superconducting phenomena in schools [1-4].

Experimental problem solving on Meissner levitation and breakdown of the resistivity of the superconductors at phase transition for the exploration of the ideal properties of a conductor have been proposed to students of Italian secondary schools, with the use of worksheets tutorials that implement inquiry based learning strategies.[5-6].

The students’ initial conceptions about how an ideal conductor dynamically interacts with a magnet in motion, as these conceptions are modified by the phenomenological exploration and how they are structured at the end of the learning path were monitored with pre-test, post-test focused on conceptual issues explored experimentally.

The results evidence that students initially believe that an ideal conductor is a transparent medium to the magnetic field. The exploration of analogical situations of suspension and deceleration of magnets activate in students the recognition of the nature of ideal diamagnet of a superconductor.

Sverdlov Roman (IISER)

Can “infinitesimal” epsilon in path integral propagator actually be finite?

Professor Mikhail Mensky, and, more recently, Adrian Kent, has discussed a possibility of a continuous measurement model involving “restricted path integrals”. Instead of computing the probability of “out state” at $t = +\infty$, we are computing a probability of a trajectory $\phi = \phi_{cl}$ taking place over entire space and time. The probability of said trajectory is given by “restricted path integral” around a “corridor” surrounding $\phi_{cl}$. The “size” of said corridor is “very large” on quantum scale (thus explaining unbounded path integral) and “very small” on classical scale (thus explaining emergence of “classical” trajectory). Said “corridor” can be replaced by Gaussian “weight” attached to path integral. My own contribution to the above idea involves the realization that said “Gaussian weight” can be interpreted as an “infinitesimal” $\epsilon$ parameter used in QFT propagators. Thus, a statement that “$\epsilon$ is infinitesimal” is logically equivalent to the statement “classical scale is infinitely large” which, in fact, is a default assumption of quantum physics. On the other hand, since we know that classical scale is finite, we can compute the finite (but very small) value of $\epsilon$ and predict deviations to quantum predictions on all scales (although on quantum scales such deviations are very small, and they became large on classical scales). The mathematical derivation of the above phenomenon is given in [1].

References

Realistic interpretation of Grassmann variables outside the integral sign

While Grassmann integration is “formally” defined its properties are counter intuitive. Why would integral of an odd function give non-zero value and integral of an even function be zero? Why would the integral of the exponential be proportional to the coefficient in the exponentiation rather than inversely proportional? How can Grassmann integral possibly be real or complex? After all, taking real/complex number to arbitrarily high power would never produce zero, while taking polynomial of products of Grassmann numbers would (and “integral” should be a limit of such polynomial if it is to be viewed as “limit of the sum”). Of course, none of it is an issue if integral is simply viewed as an operator AS OPPOSED TO limit of the sum. But describing it as limit of the sum seems very problematic. In this talk, we will attempt to do the latter. We consider a space with infinite dimensionality, and in this space we draw a contour with infinitely many turns, each turn having infinitesimal length. We also consider two different kinds of products: dot product and wedge product. In case of both products, the vectors directed along different axes anticommute; but the difference is that if we take a product of unit vector with itself, then the wedge product will return zero and dot product will return 1. Finally, we take Manhatten metric as opposed to Euclidian. When we write down an integral, the product between “infinitesimal” and “finite” part is a dot-product, while the product inside the finite part is a wedge-product (and the product inside infinitesimal part can be either of these two). As long as that is the case, one can design the “turns” on the contour in such a way that integral along that particular contour will, in fact, coincide with expected properties of Grassmann integral. However, that will only be true regarding that particular contour, not any other. In particular, if we are to re-scale this contour, then the integral of $\theta d\theta$ will no longer be 1 but instead pick up factors coming from rescaling (which answers the question regarding integral of exponential). The description of that integral is provided at [1].

Gonçalves Bruno — Instituto Federal de Educação, Ciência e Tecnologia do Sudeste de Minas Gerais, Juiz de Fora, Brazil
Grain Julien — Institut d’Astrophysique Spatiale, Orsay, France
Greiner Walter — Frankfurt Institute for Advanced Studies, Frankfurt am Main, Germany
Guzzo Luigi — Istituto Nazionale di Astrofisica, Osservatorio Astronomico di Brera, Merate, Italy
Haba Zbigniew — Institute of Theoretical Physics, University of Wrocław, Wrocław, Poland
Haggard Hal — Centre de Physique Théorique, Marseille, France
Halzen Francis — University of Wisconsin-Madison, Madison, United States
Haro Jaume — Universitat Politècnica de Catalunya, Barcelona, Spain
Heavens Alan — Imperial College London, London, United Kingdom
Heron Paula — University of Washington, Seattle, United States
Hess Céline — Centre de Physique Théorique, Marseille, France
Hoehn Philipp — Perimeter Institute for Theoretical Physics, Waterloo, Canada
Hoelbling Christian — Bergische Universität Wuppertal, Wuppertal, Germany
Hugonie Cyril — Laboratoire Univers et Particules de Montpellier, Montpellier, France
Hui Lam — Columbia University, New York, United States

Updated on January 8, 2015
